Pacific herring

- energy conduit: zooplankton to larger predators
- food and income for many coastal communities
- stock declines, fishery closures, calls for EBFM
- how to reconcile human, ecosystem needs?**

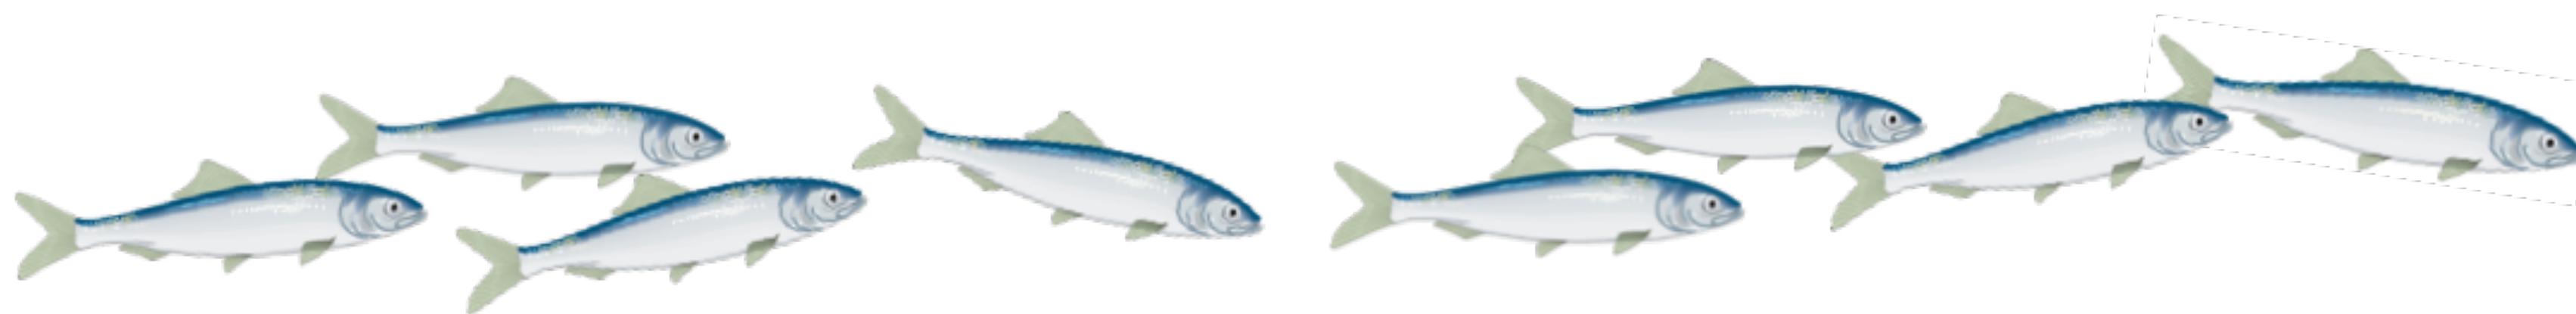

Food web modeling

- framework: Ecopath with Ecosim (EwE)
- basic principle: mass balance
- 80 functional groups
- study area: N British Columbia, Canada

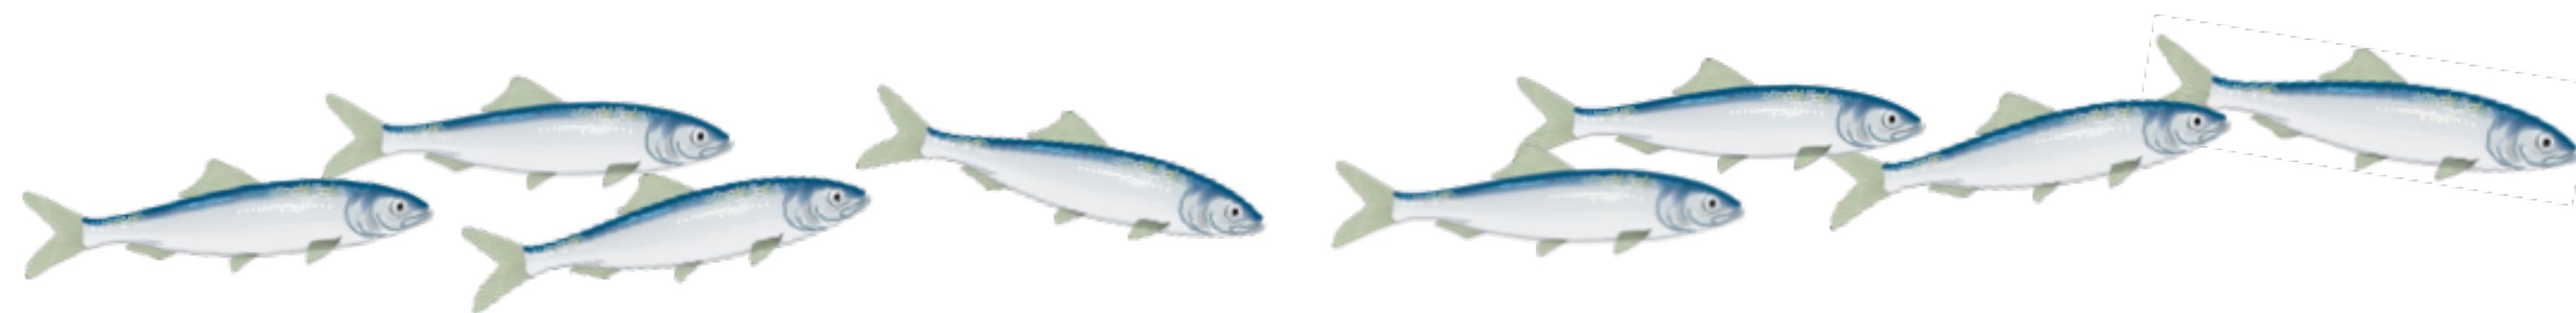

MSE in EwE

- simulates long-term strategy implementation
- compares impacts of management strategies
- places herring & fisheries in food web context
- can use ecological & socioeconomic criteria

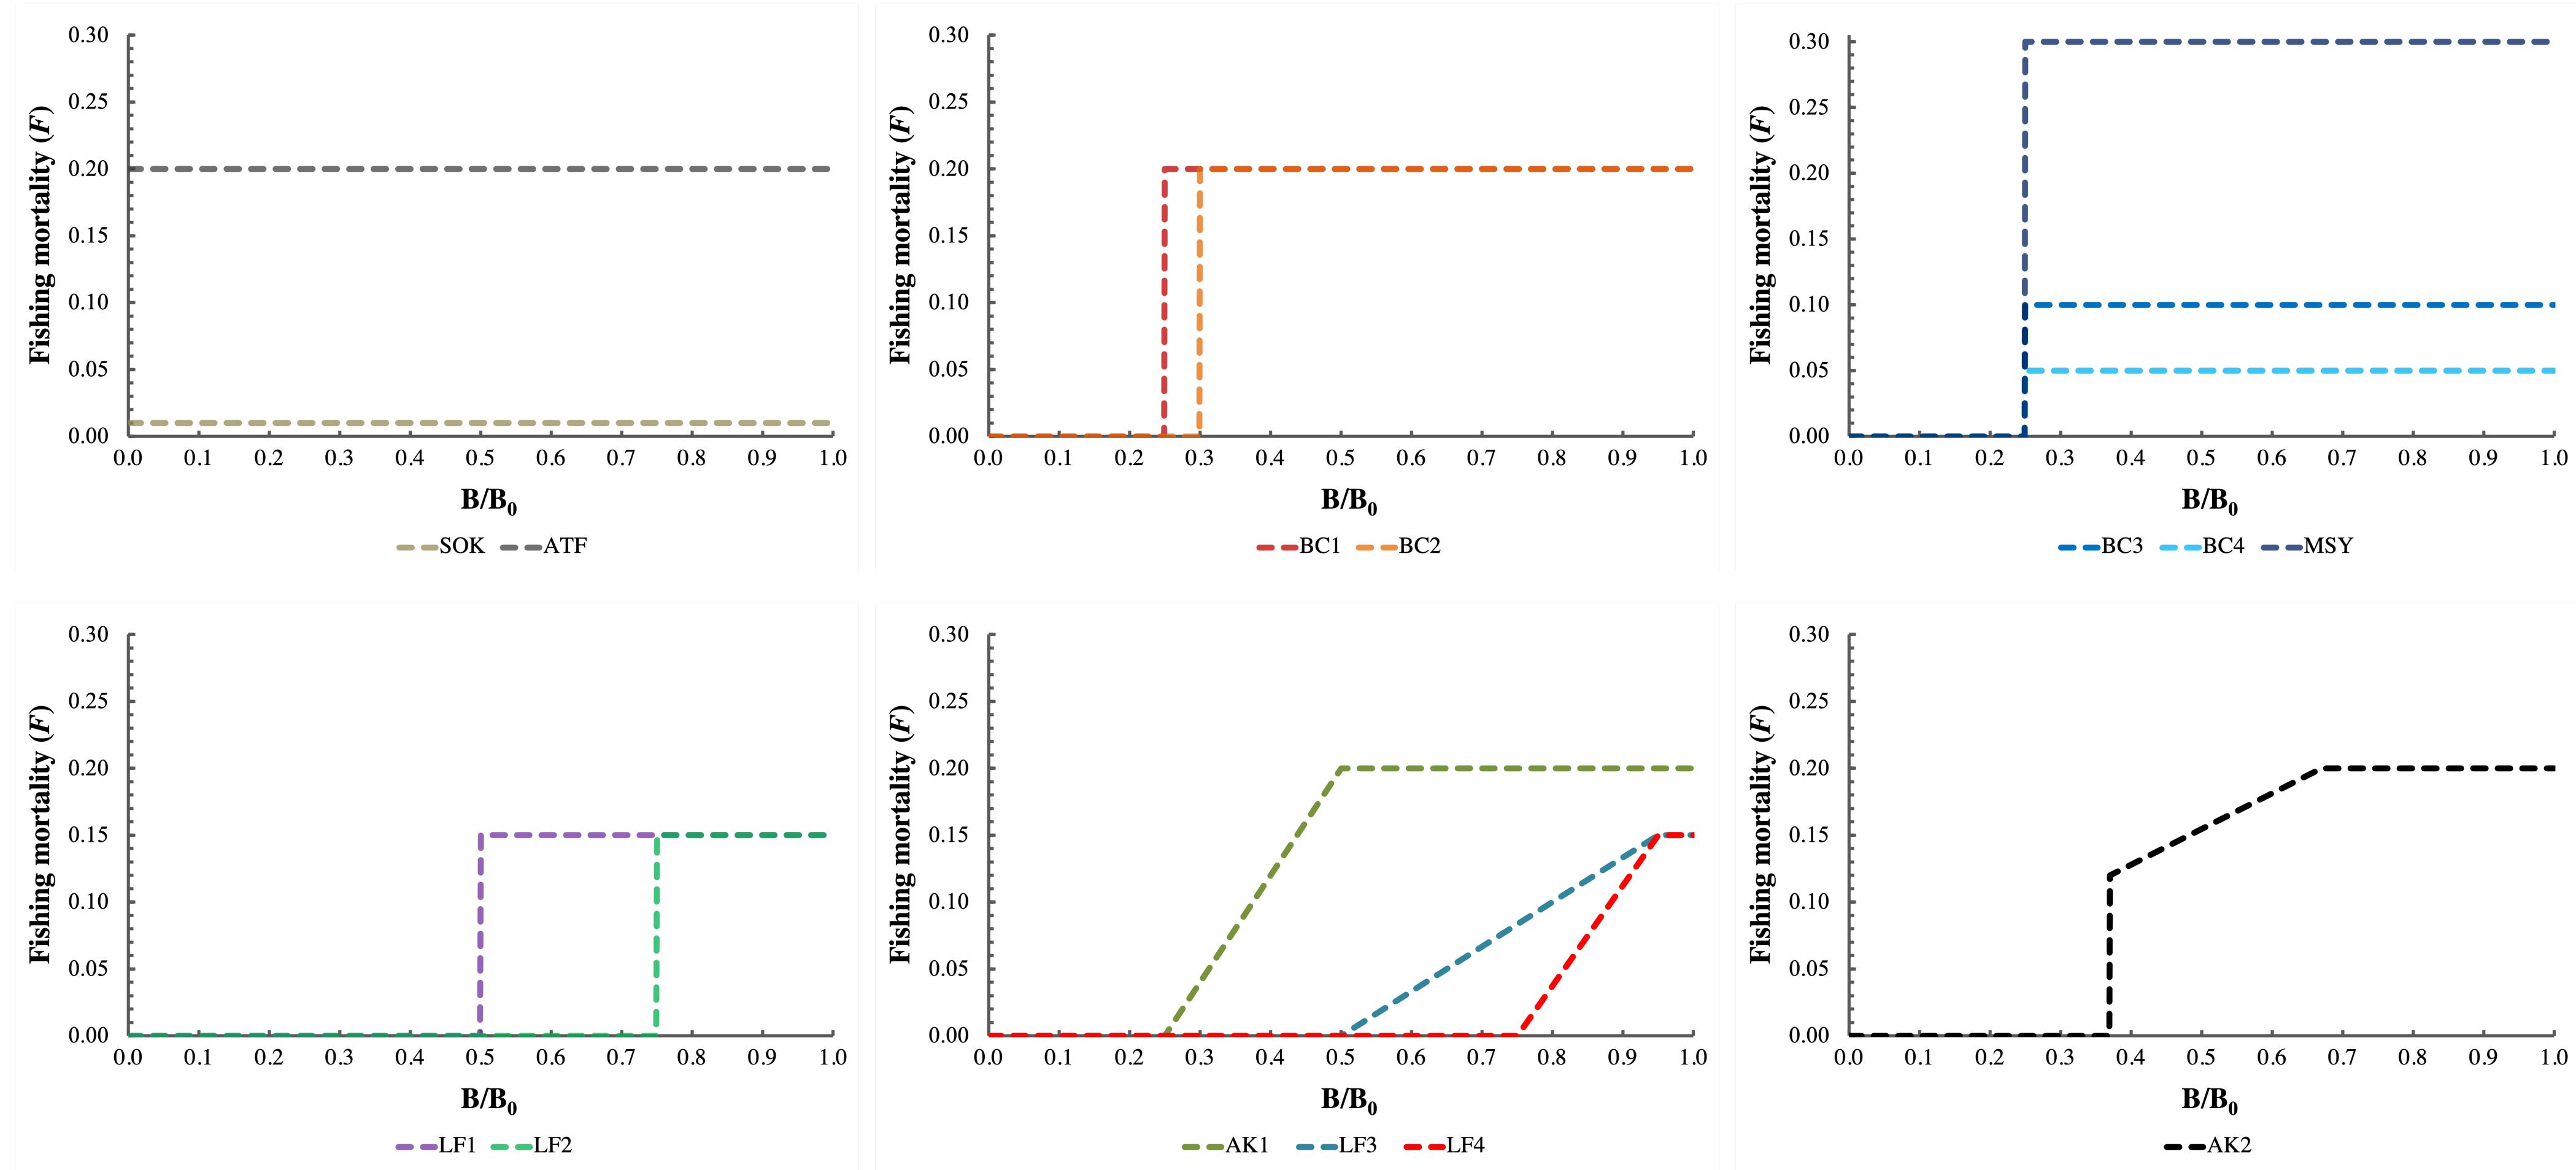

Cefas EwE MSE tool

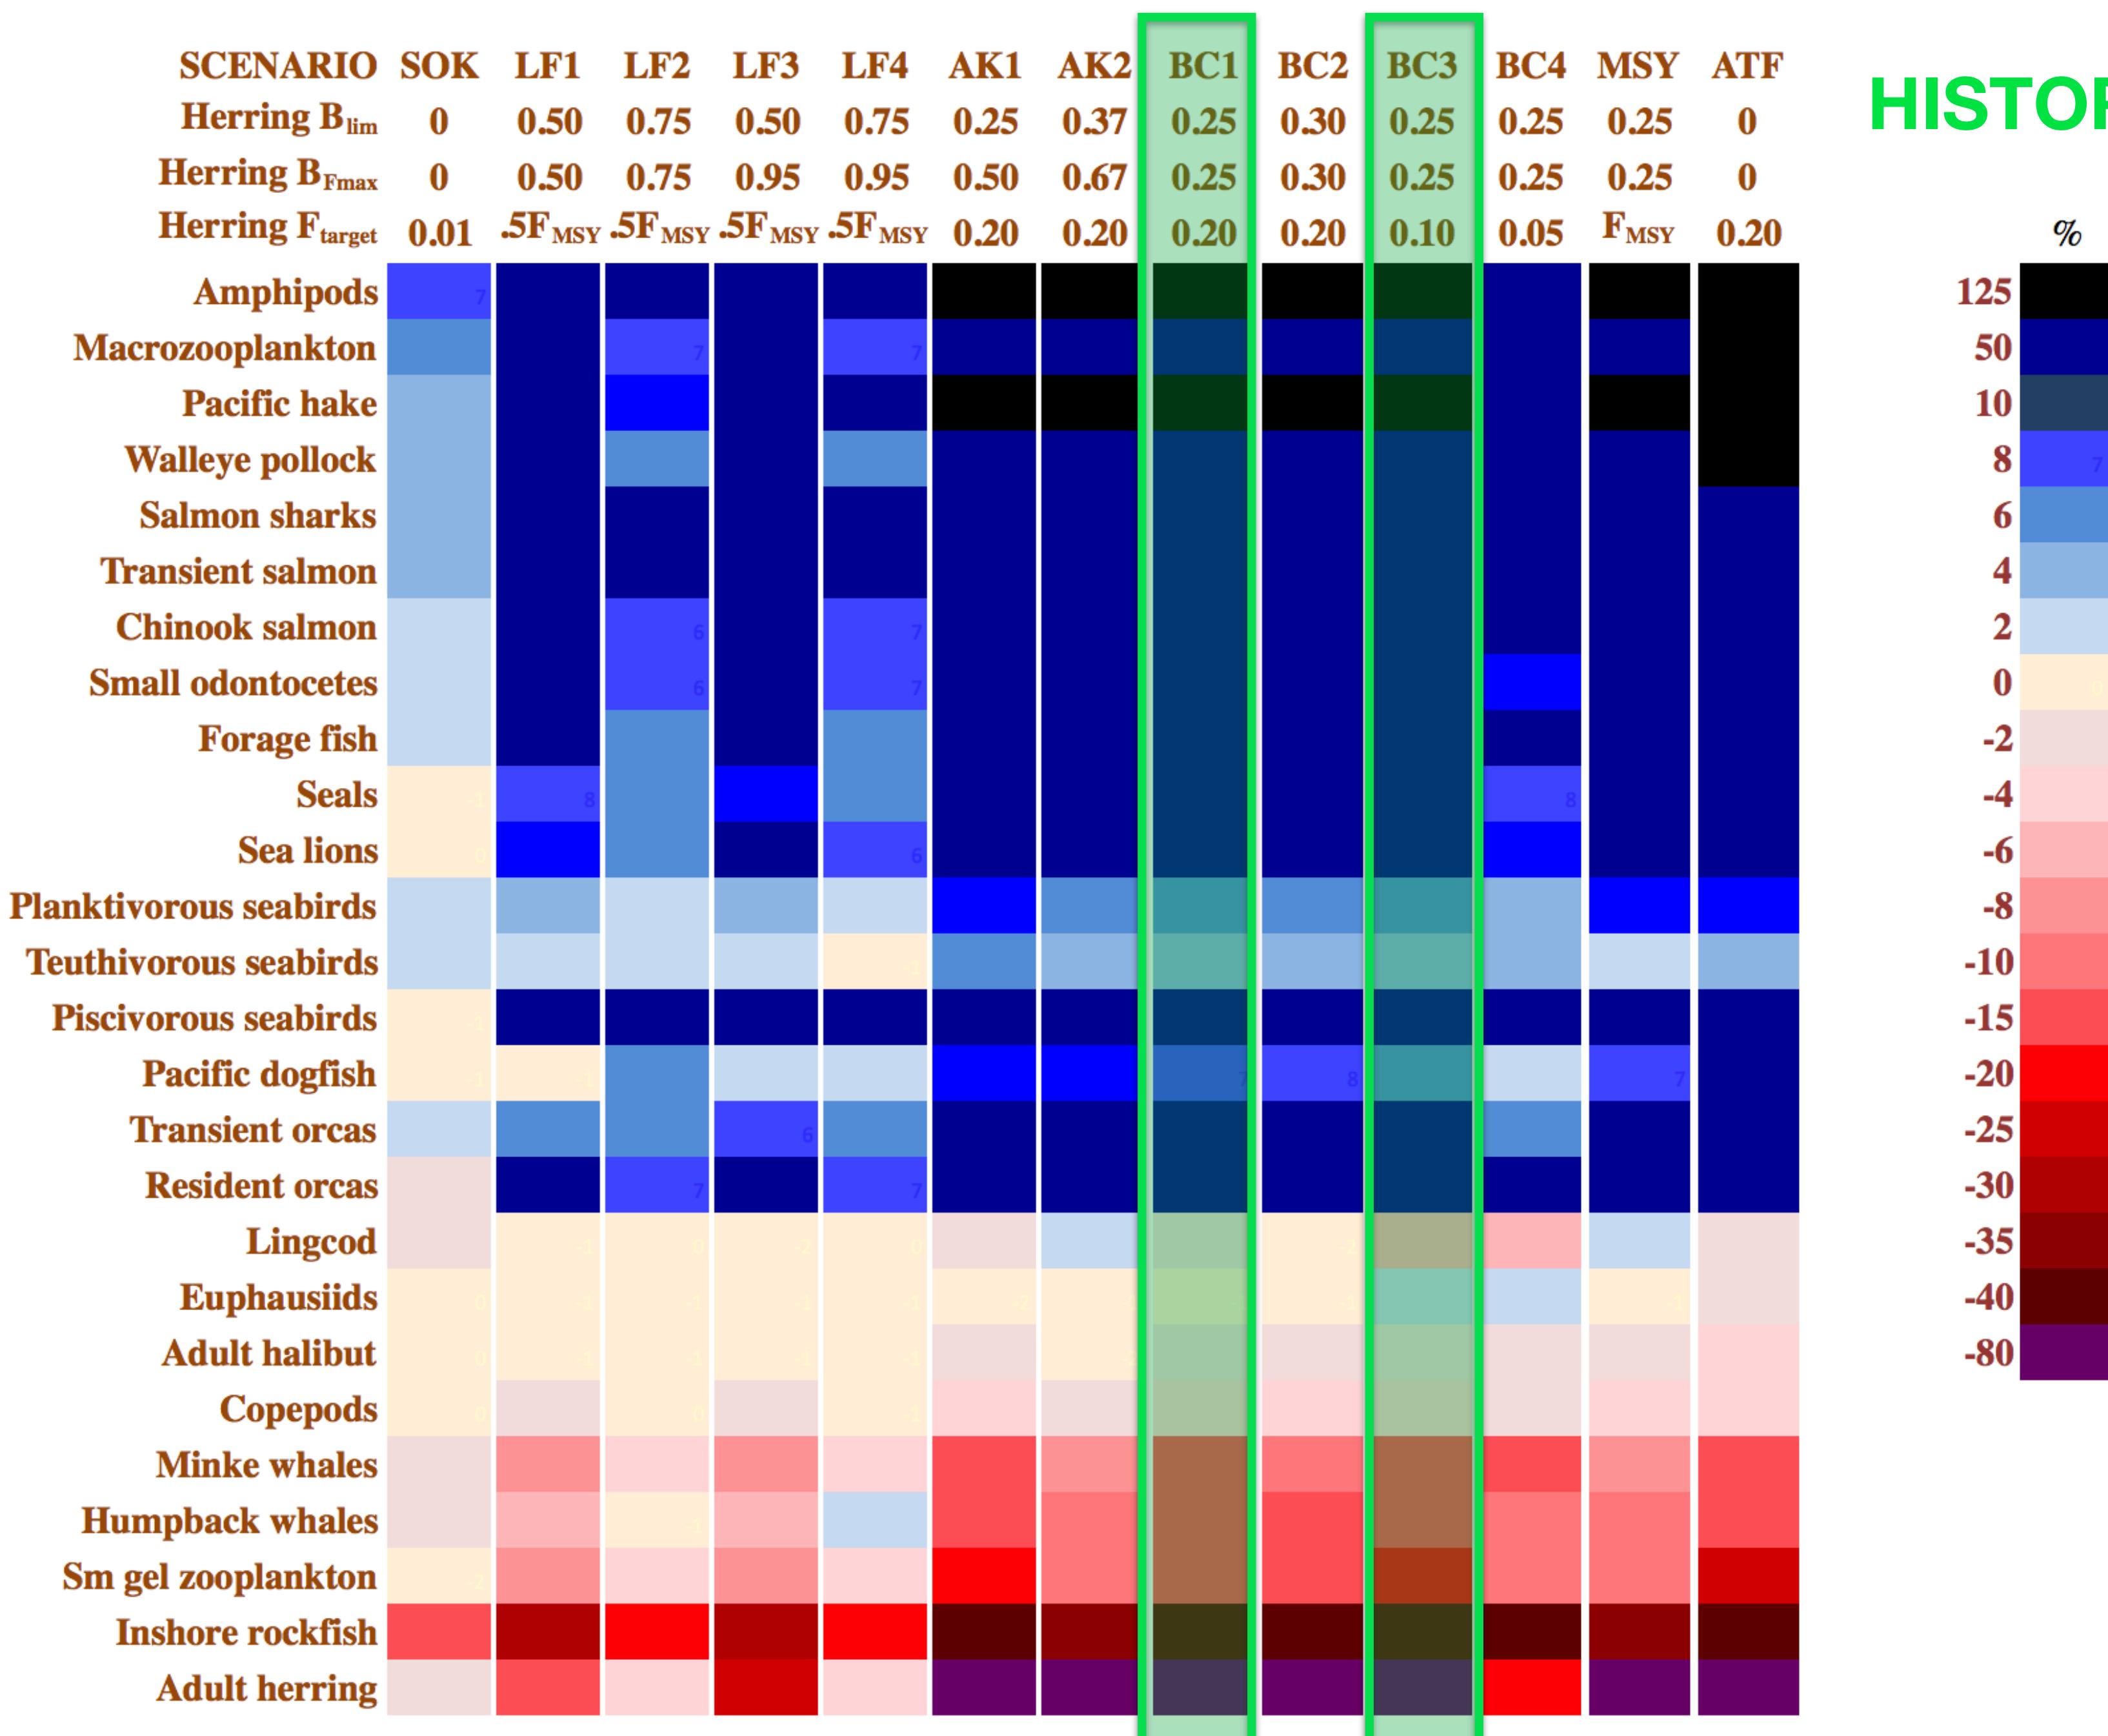

- ecosystem parameter uncertainty
- stochastic stock assesment error
- stochastic realized fishing mortality

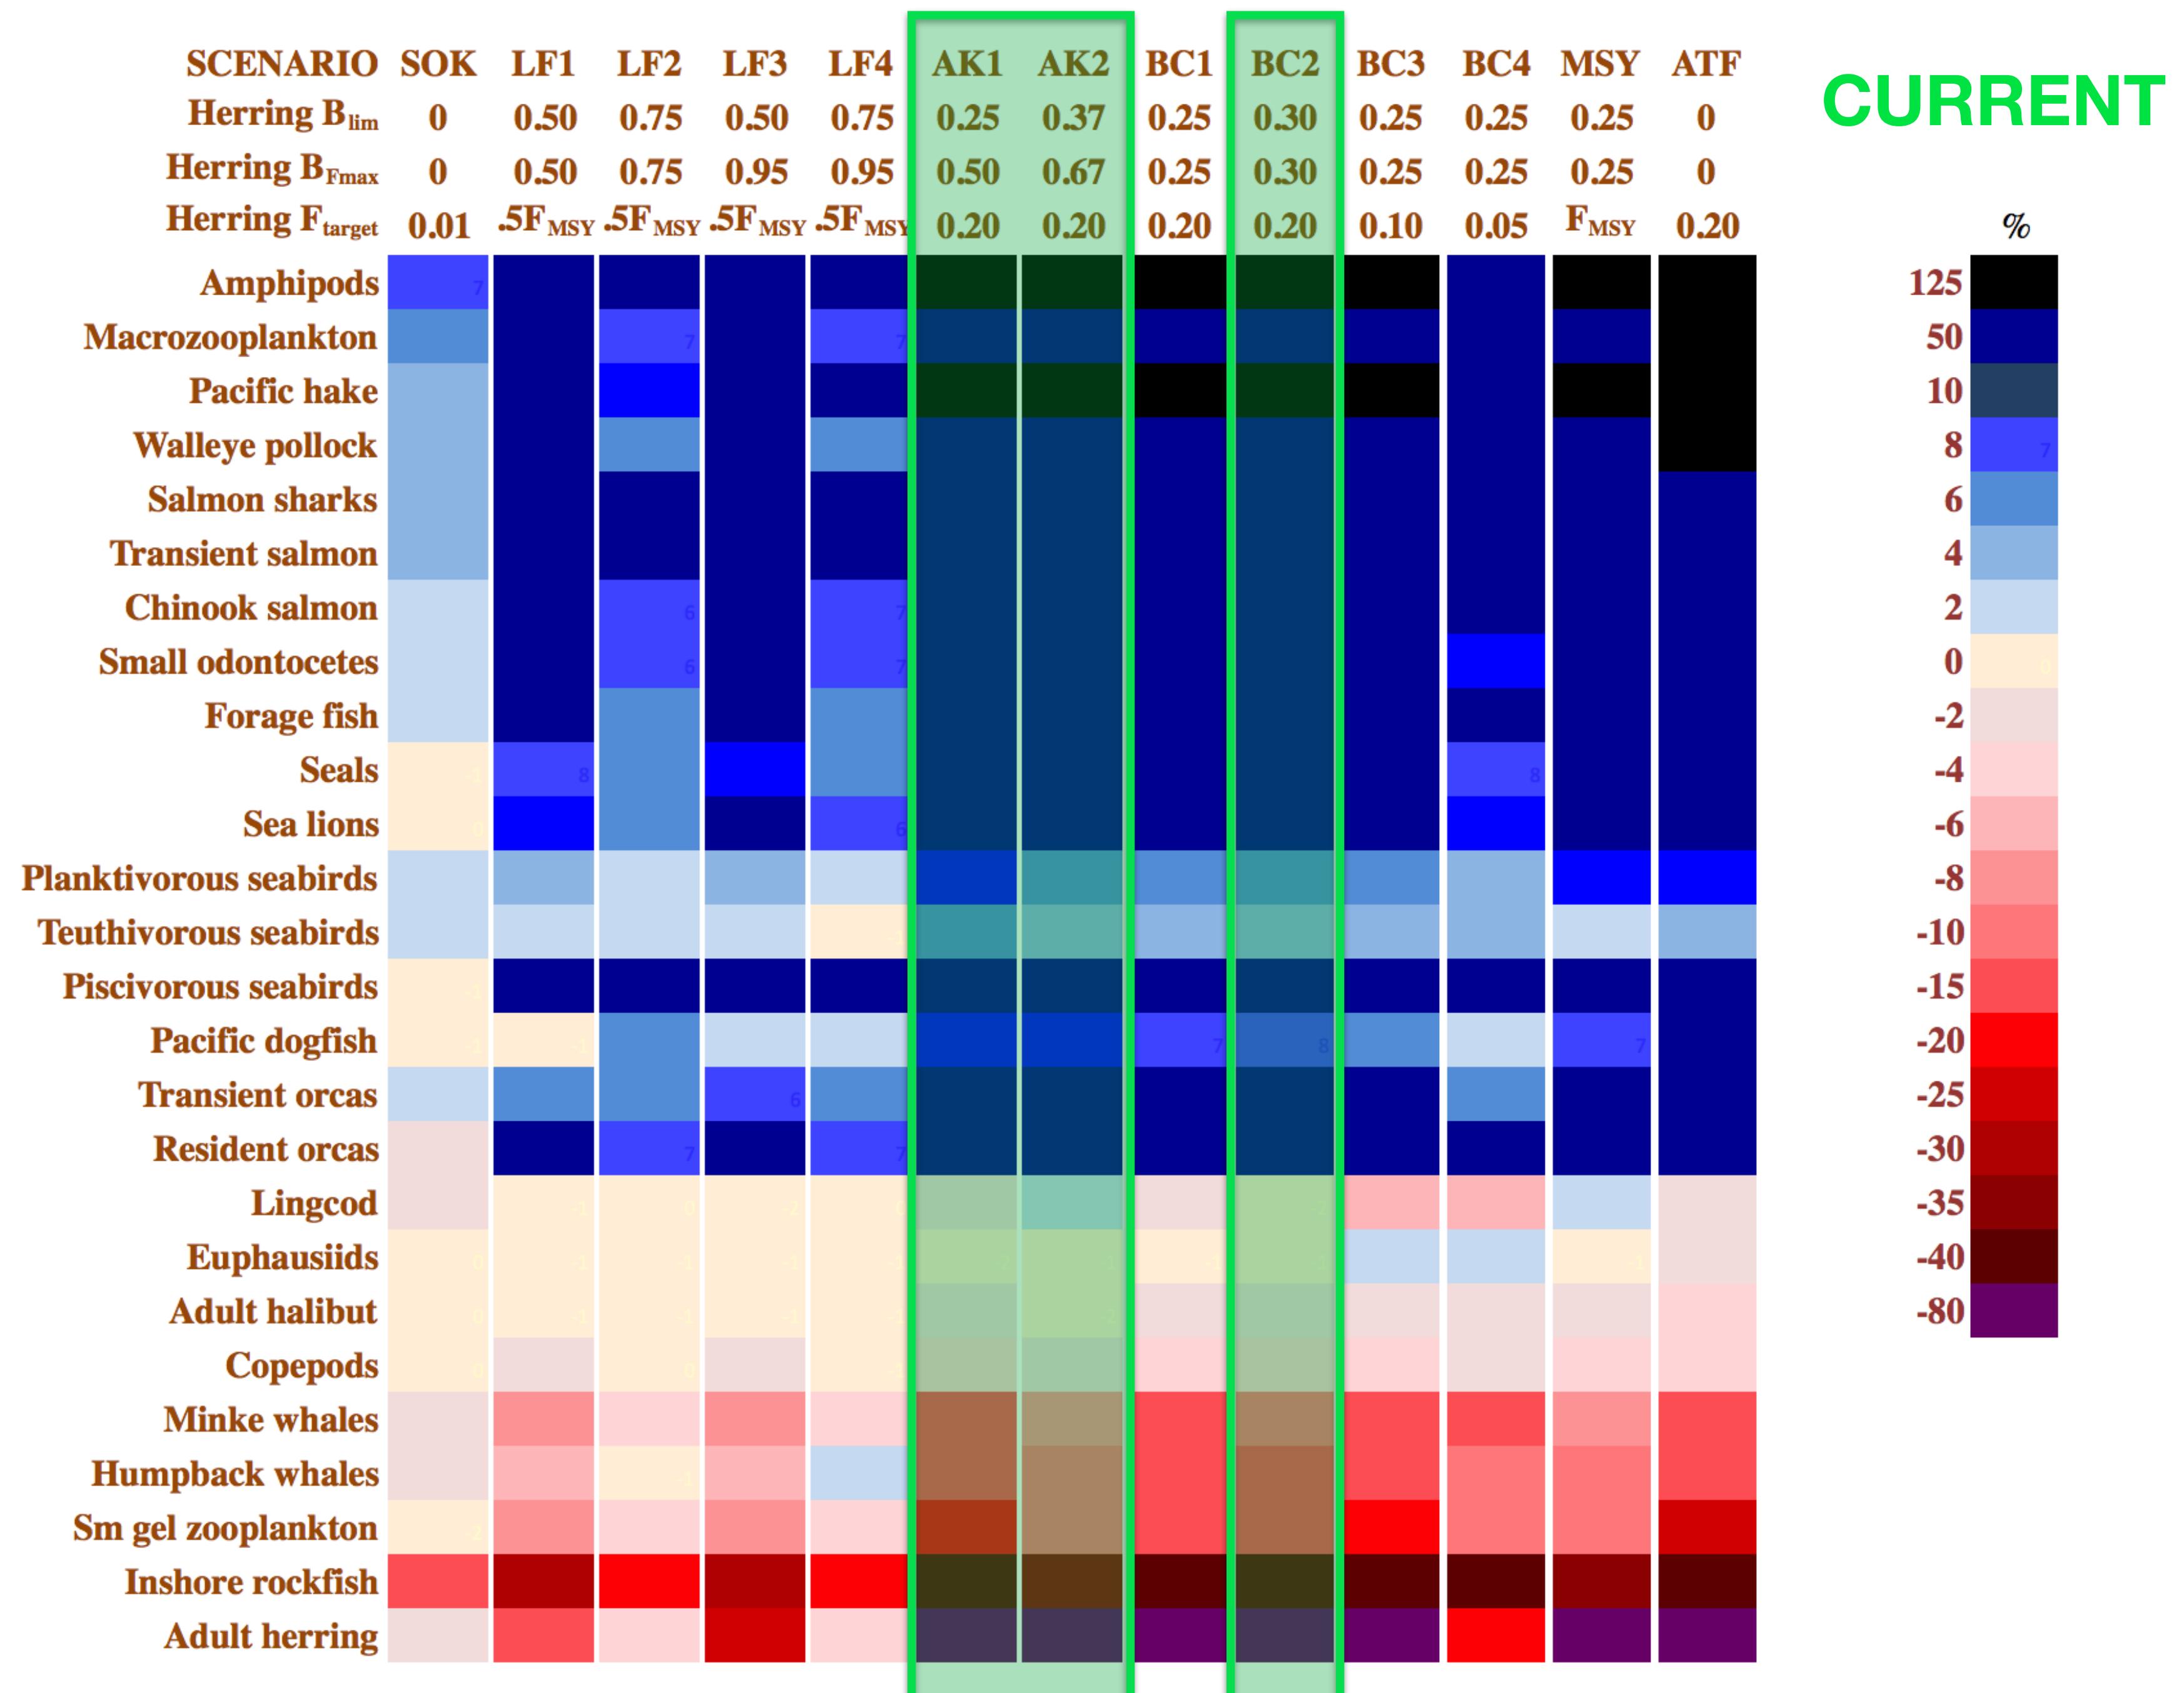

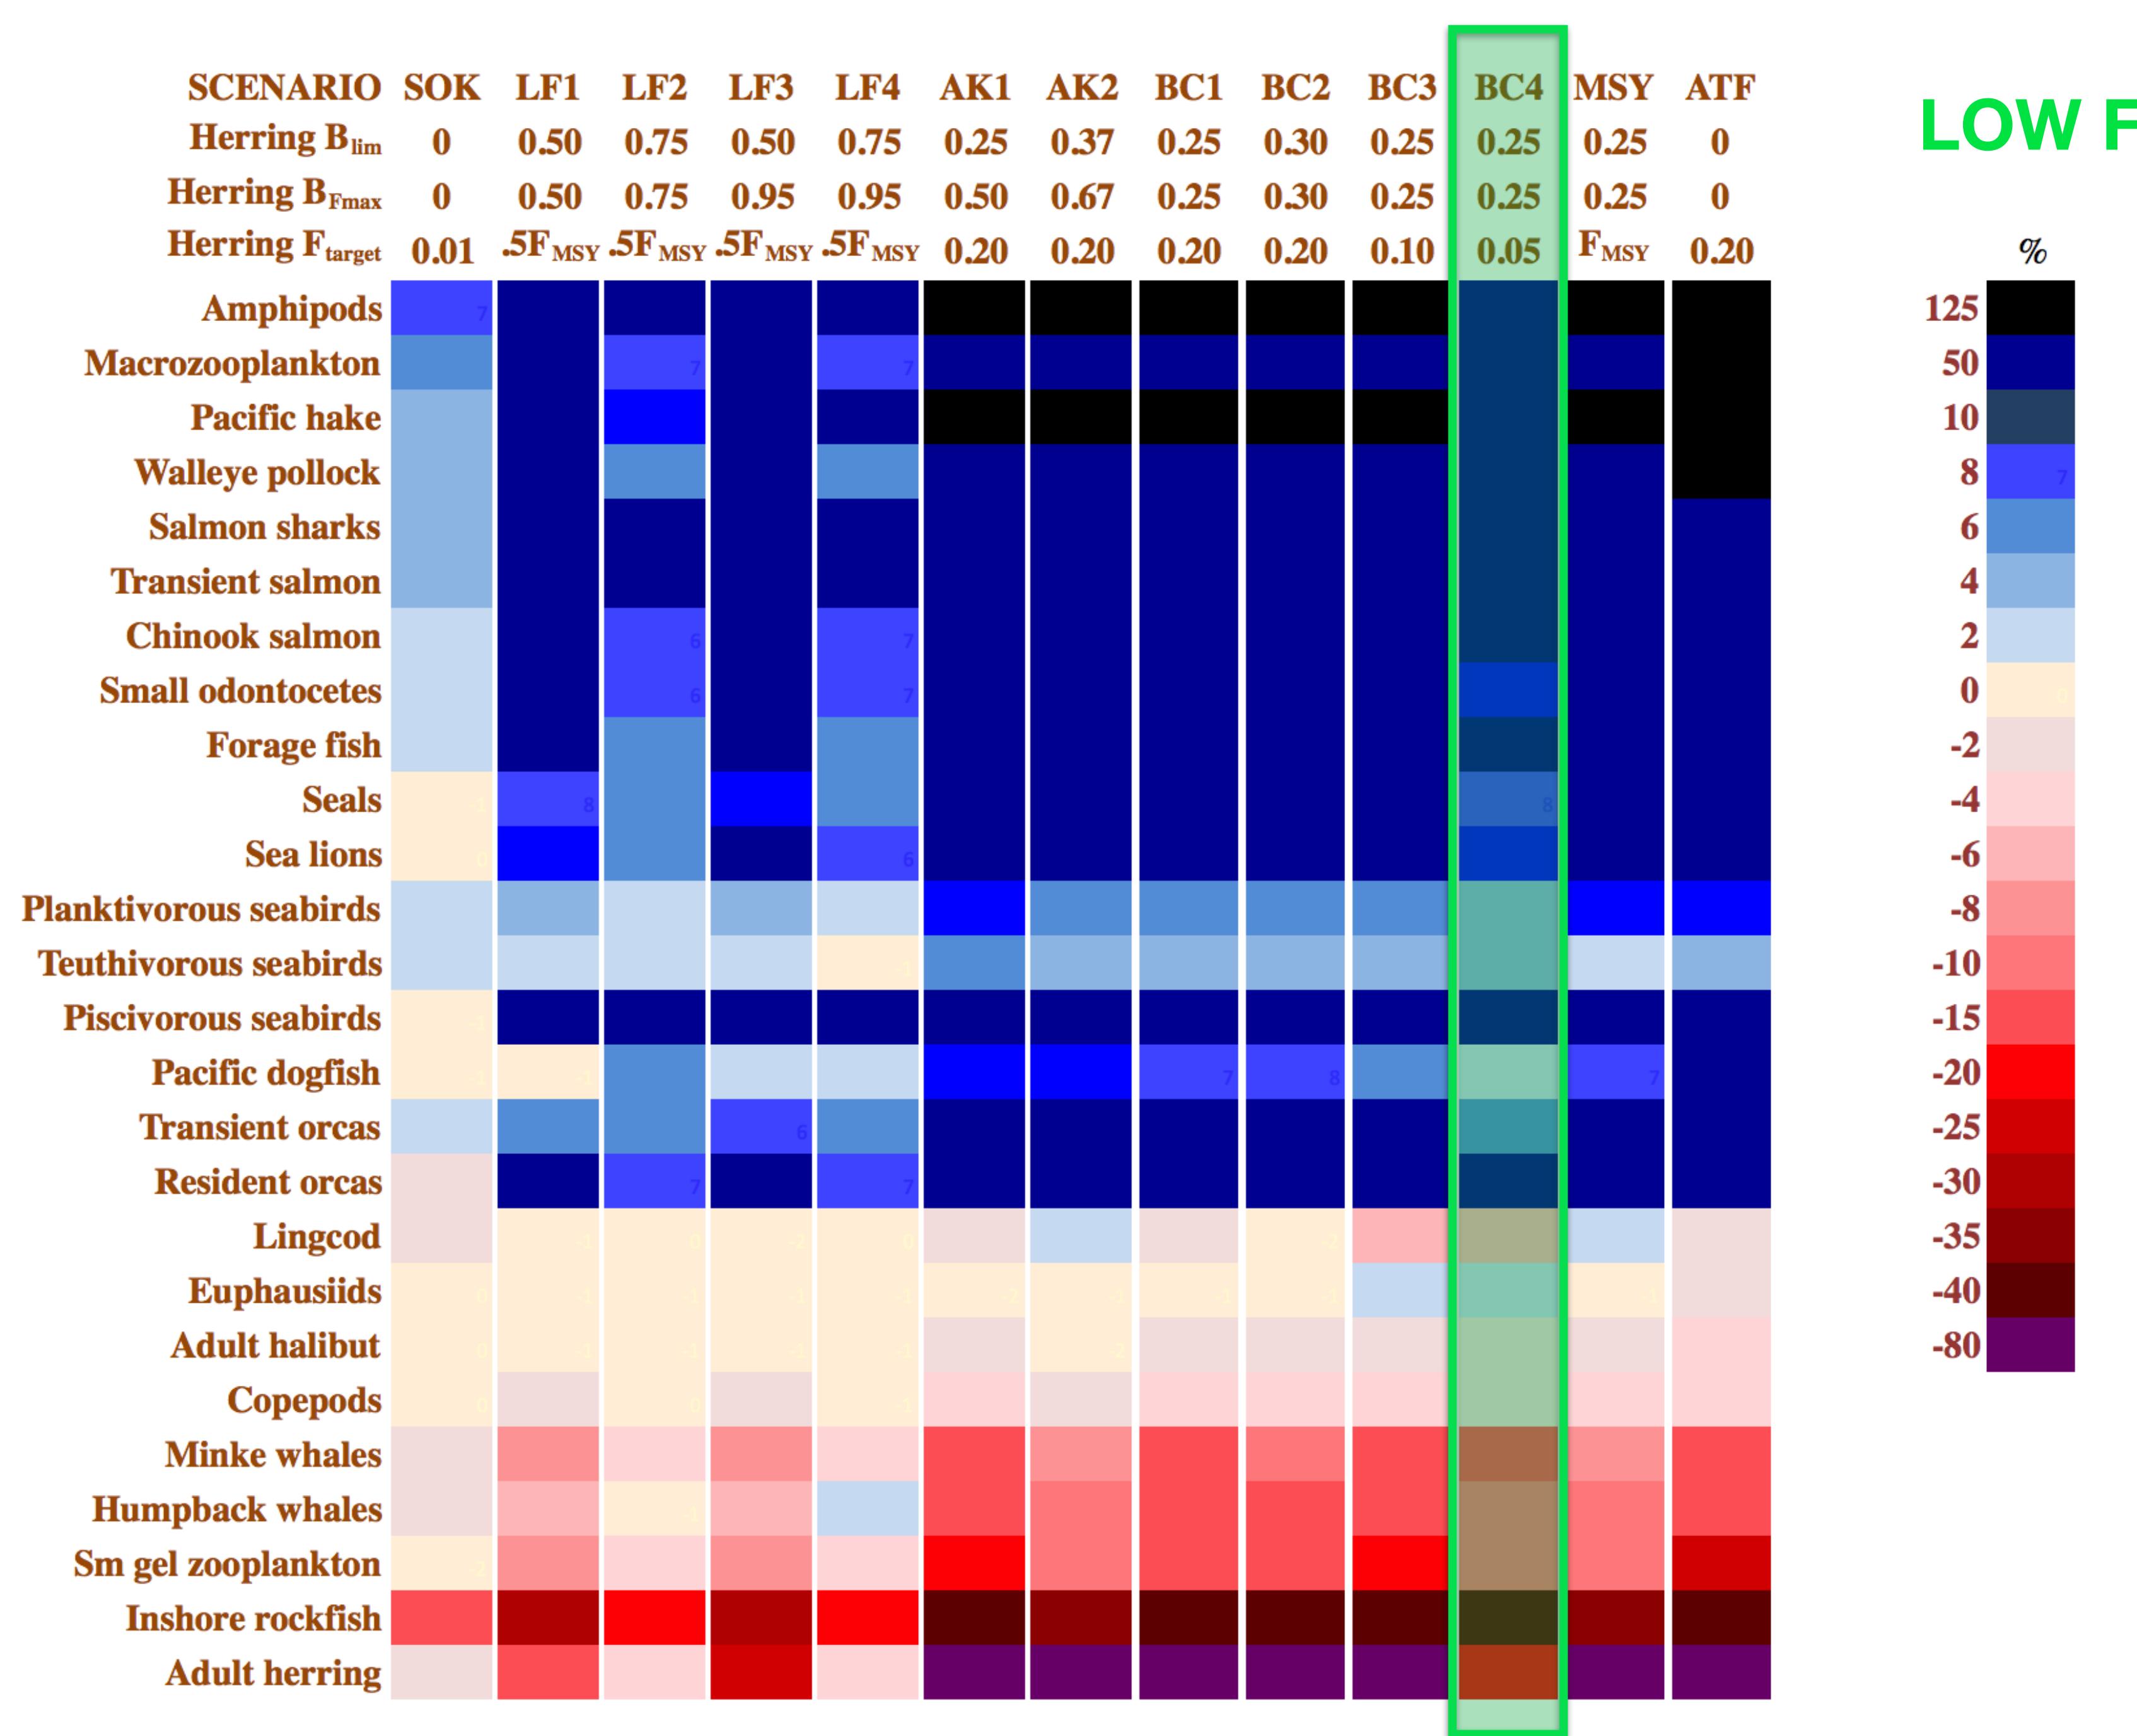

Management strategies

HISTORICAL

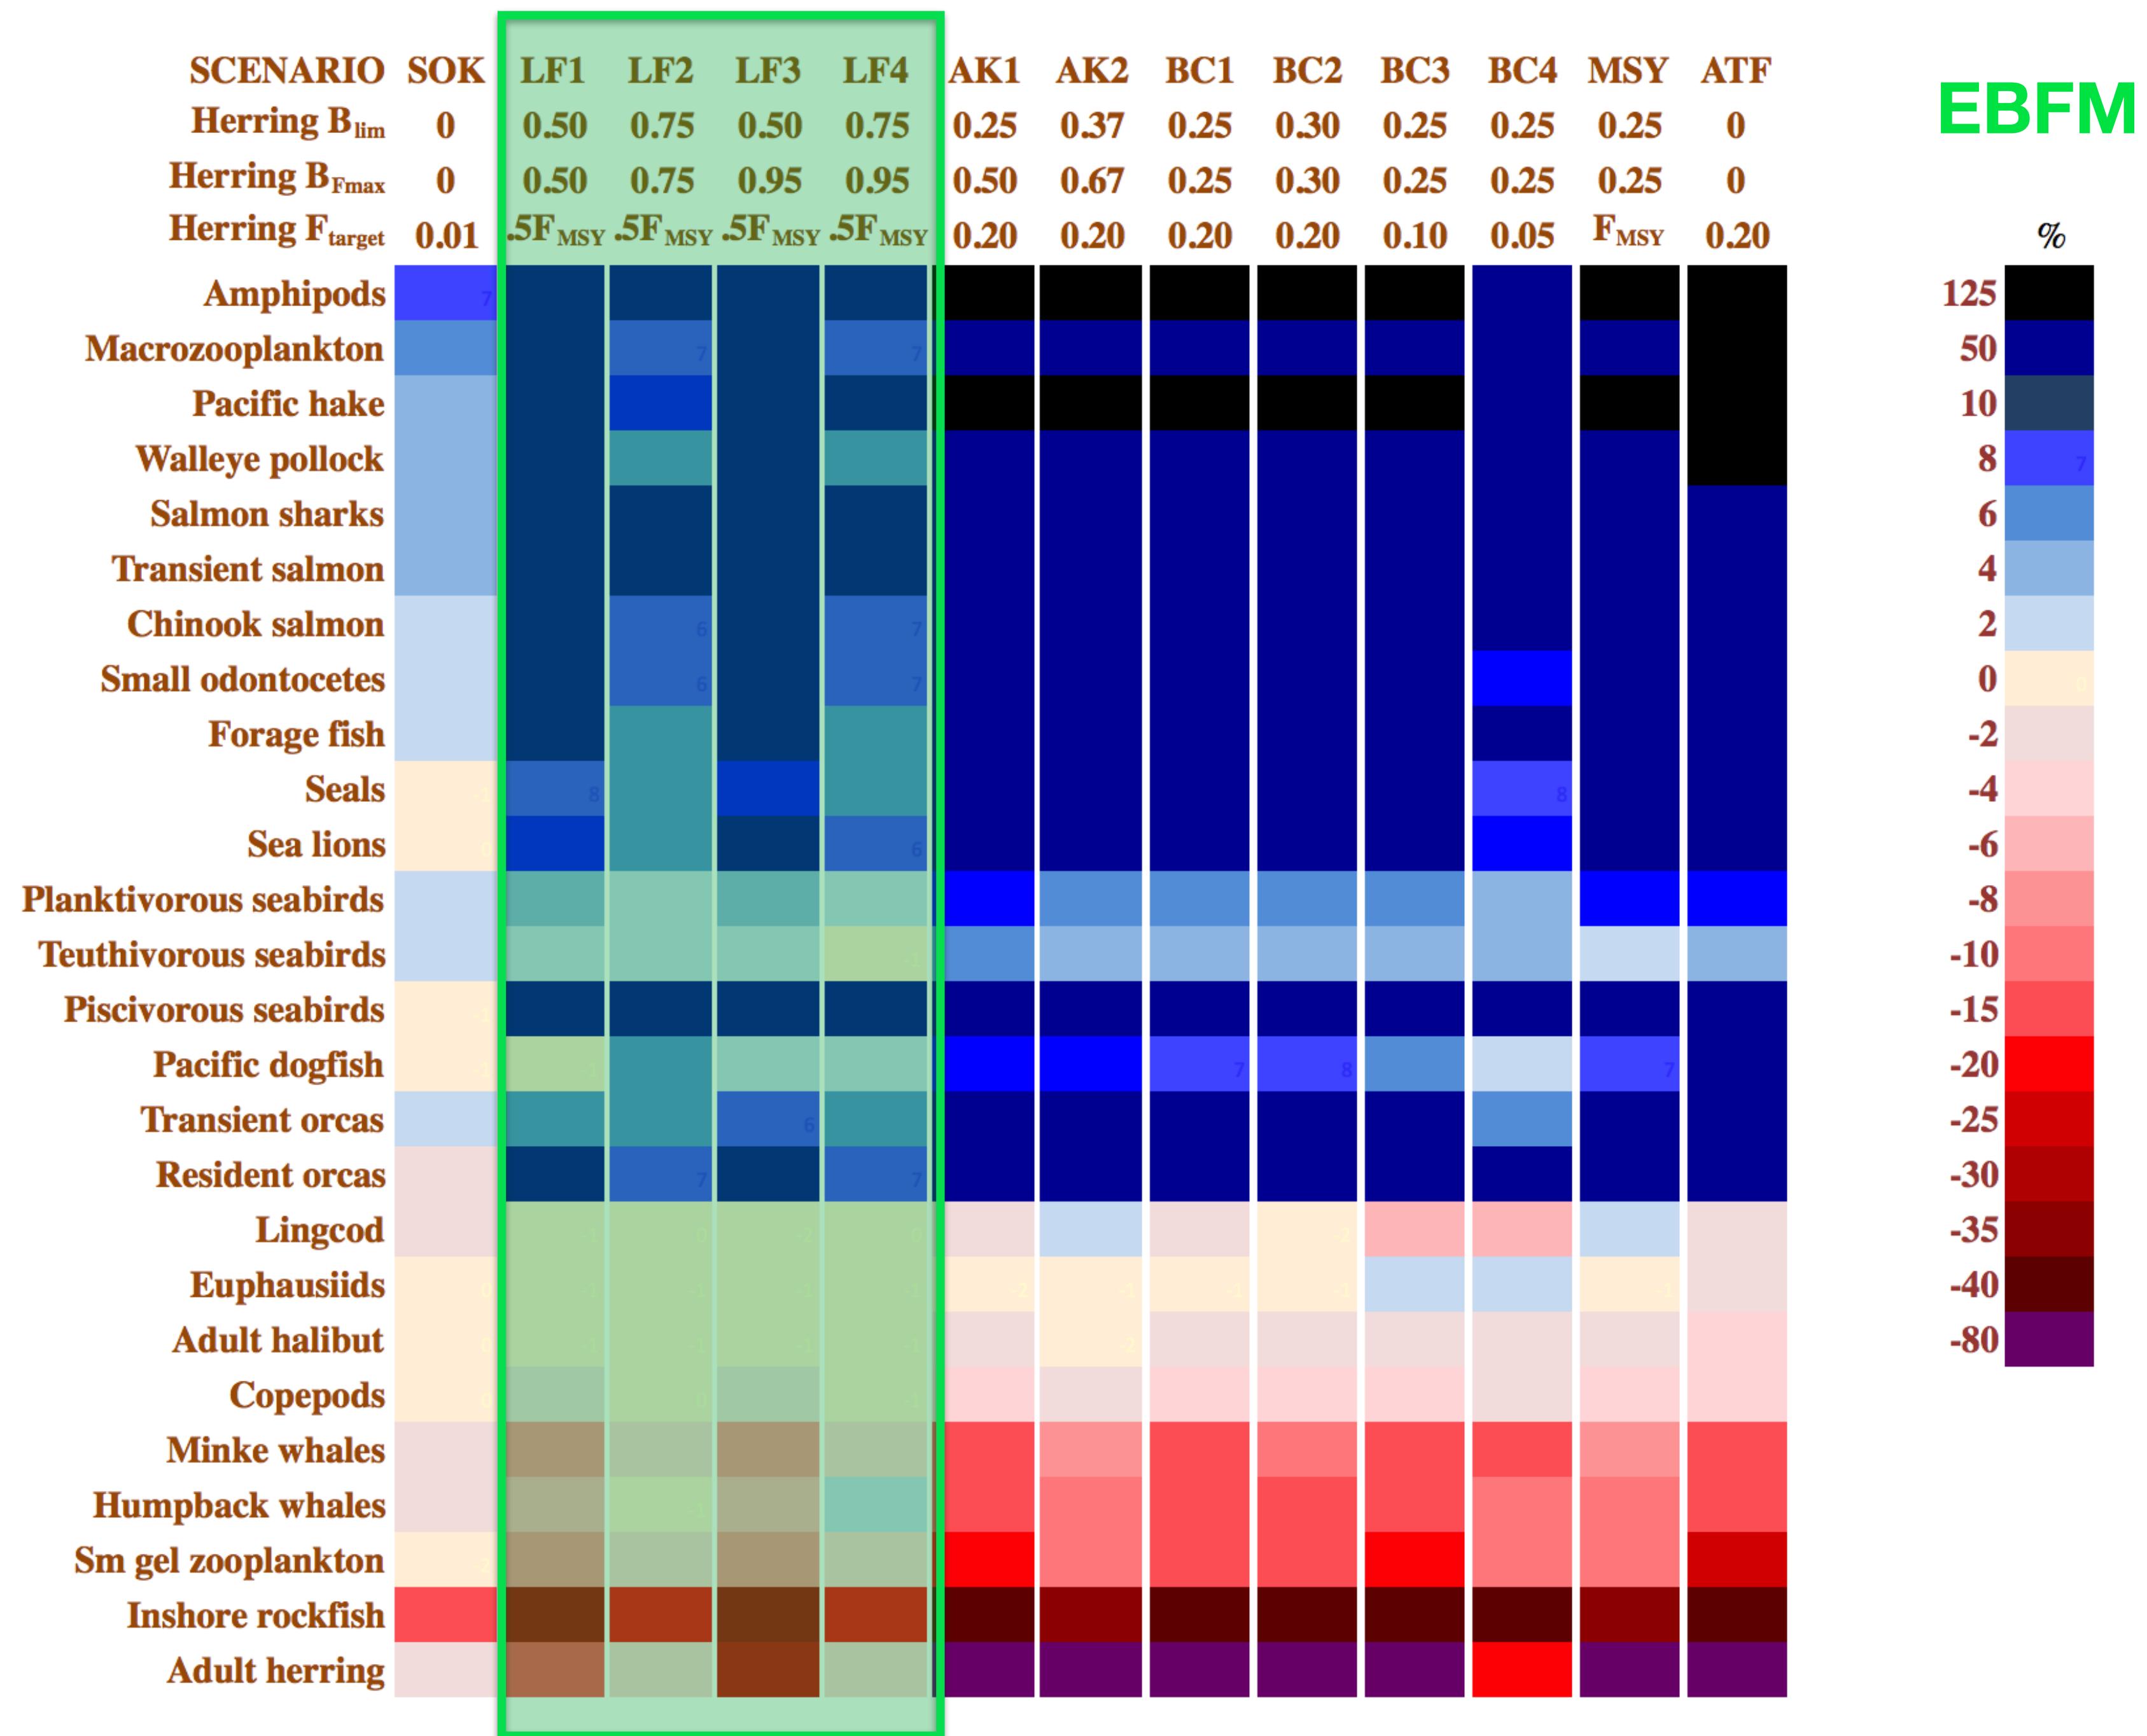

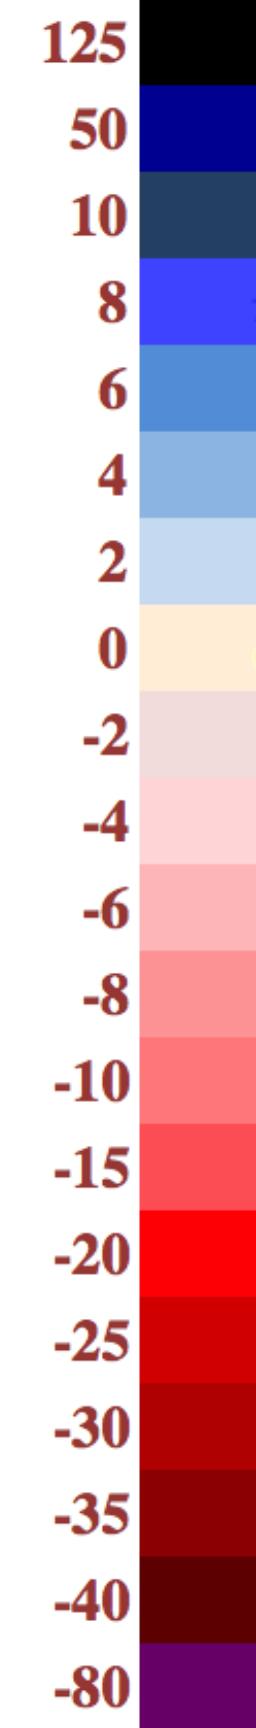

LOW F

%

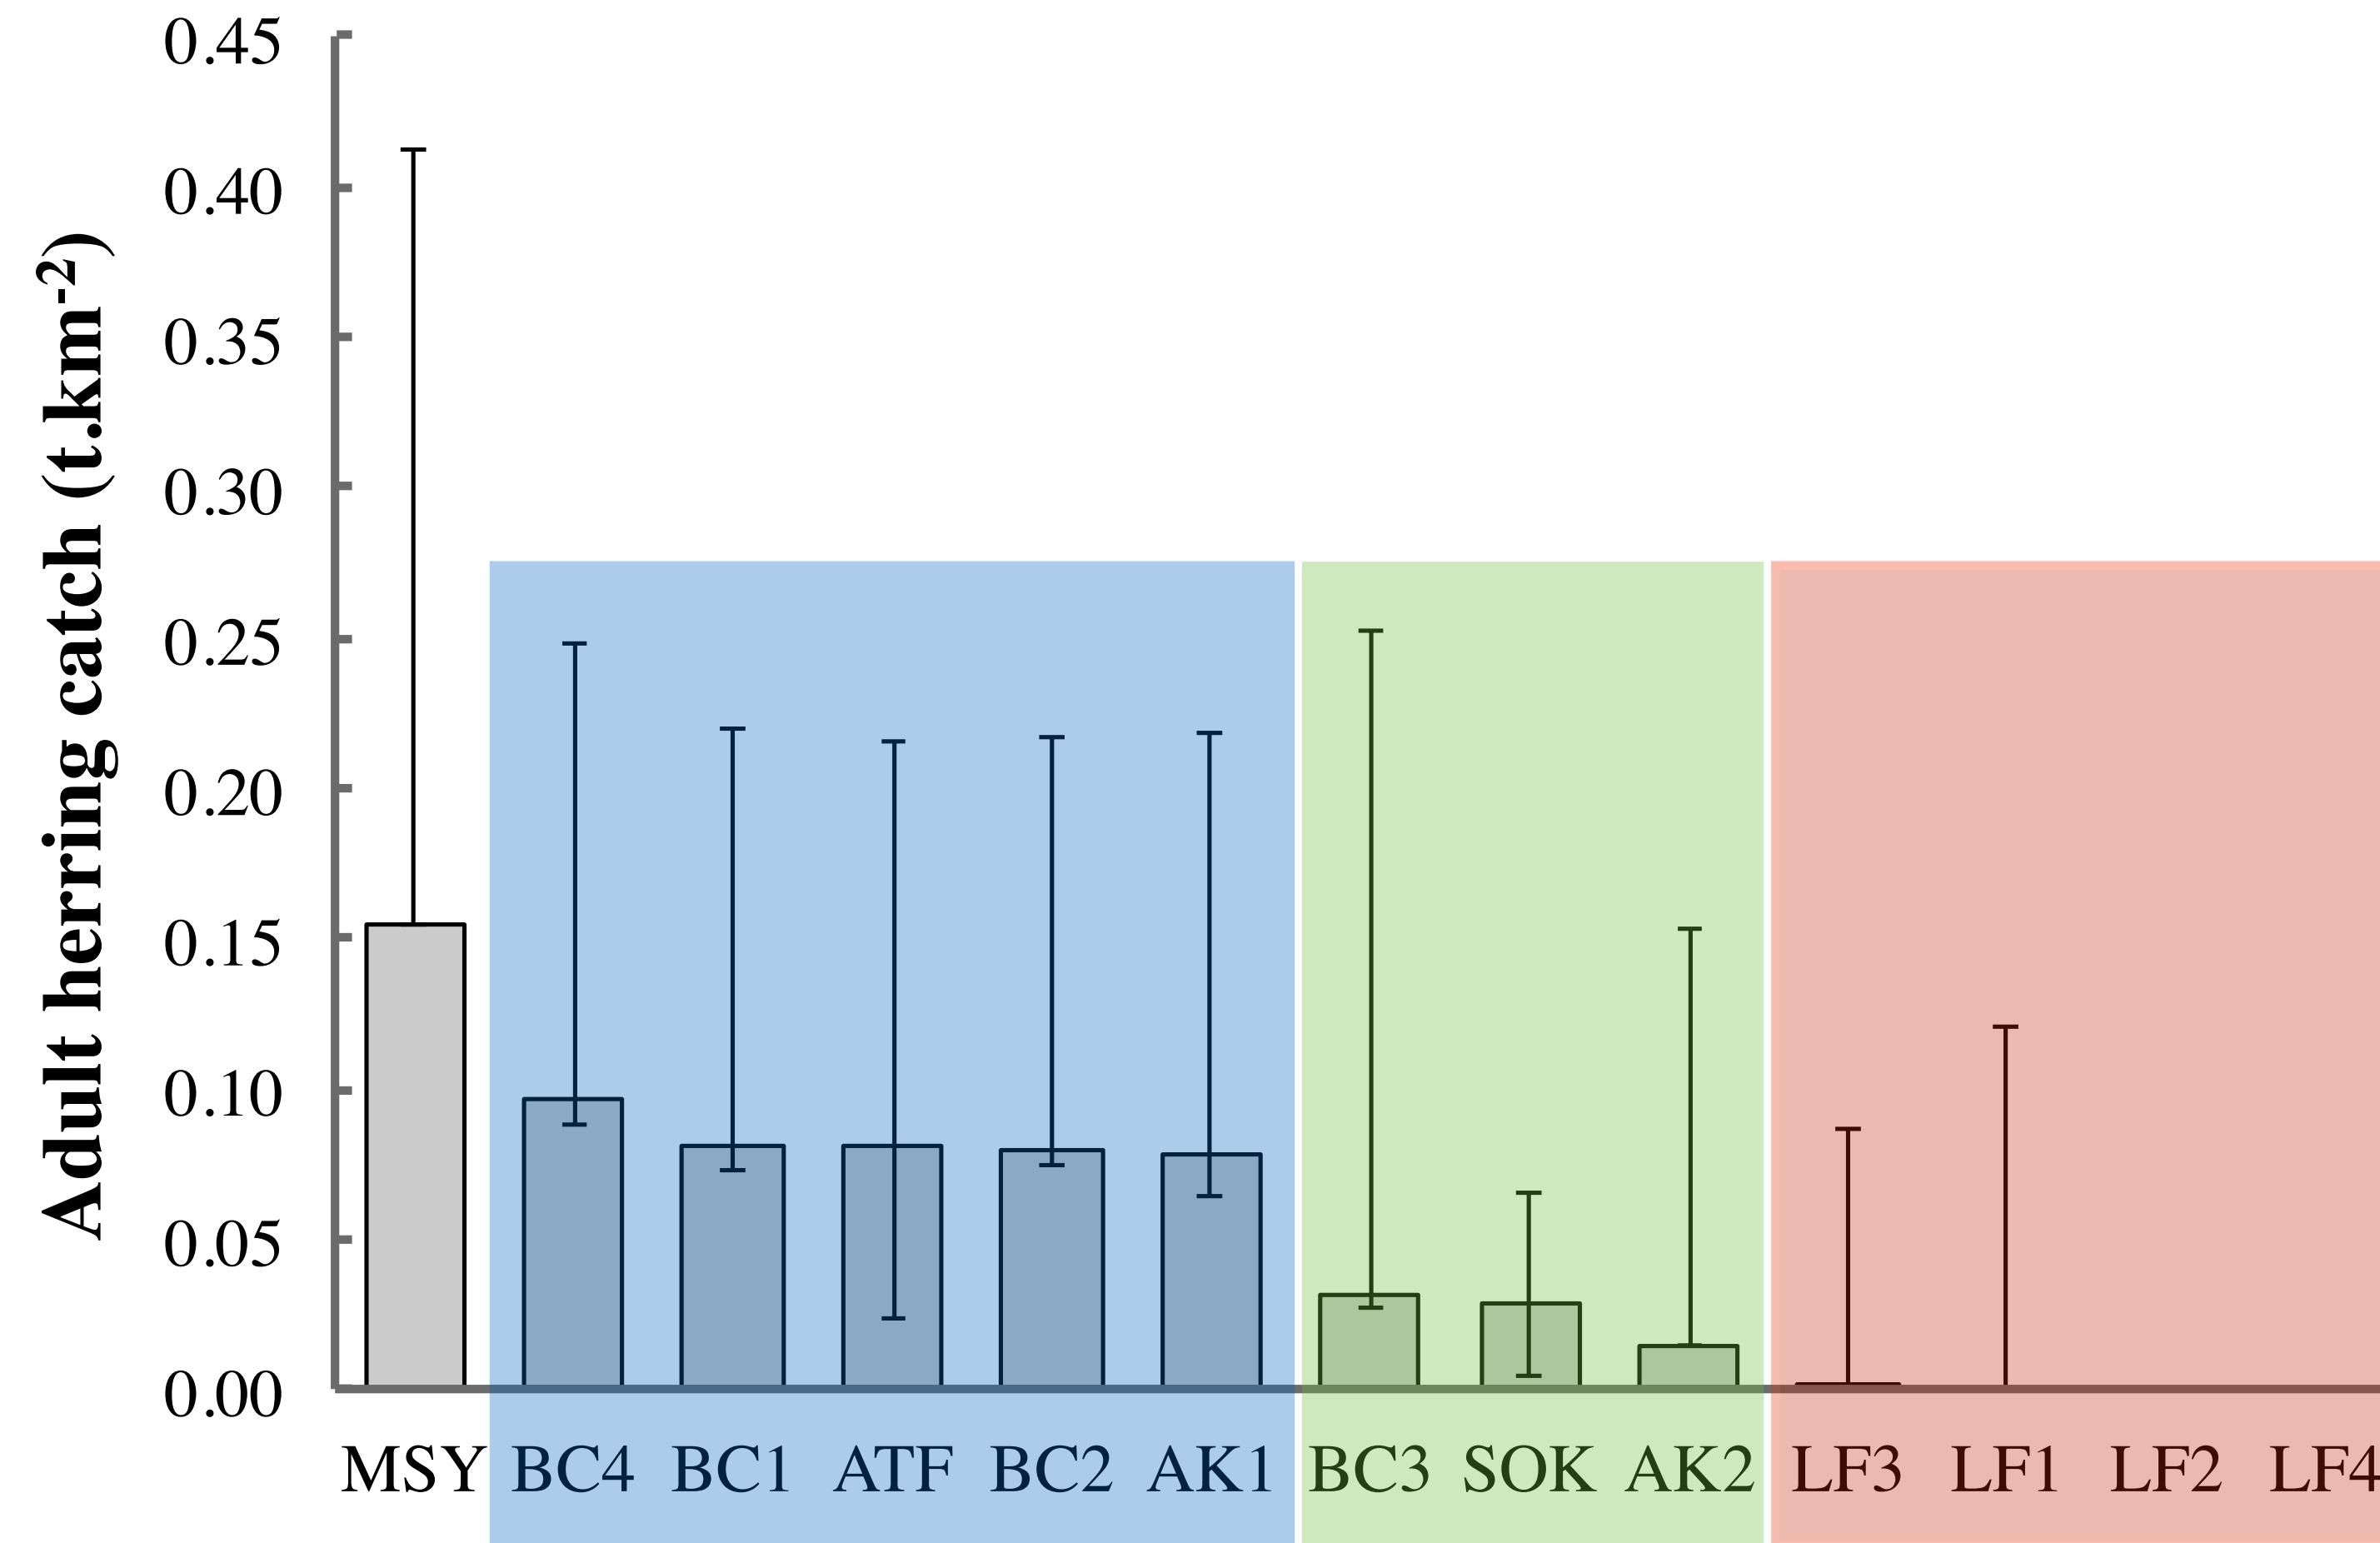

EBFM

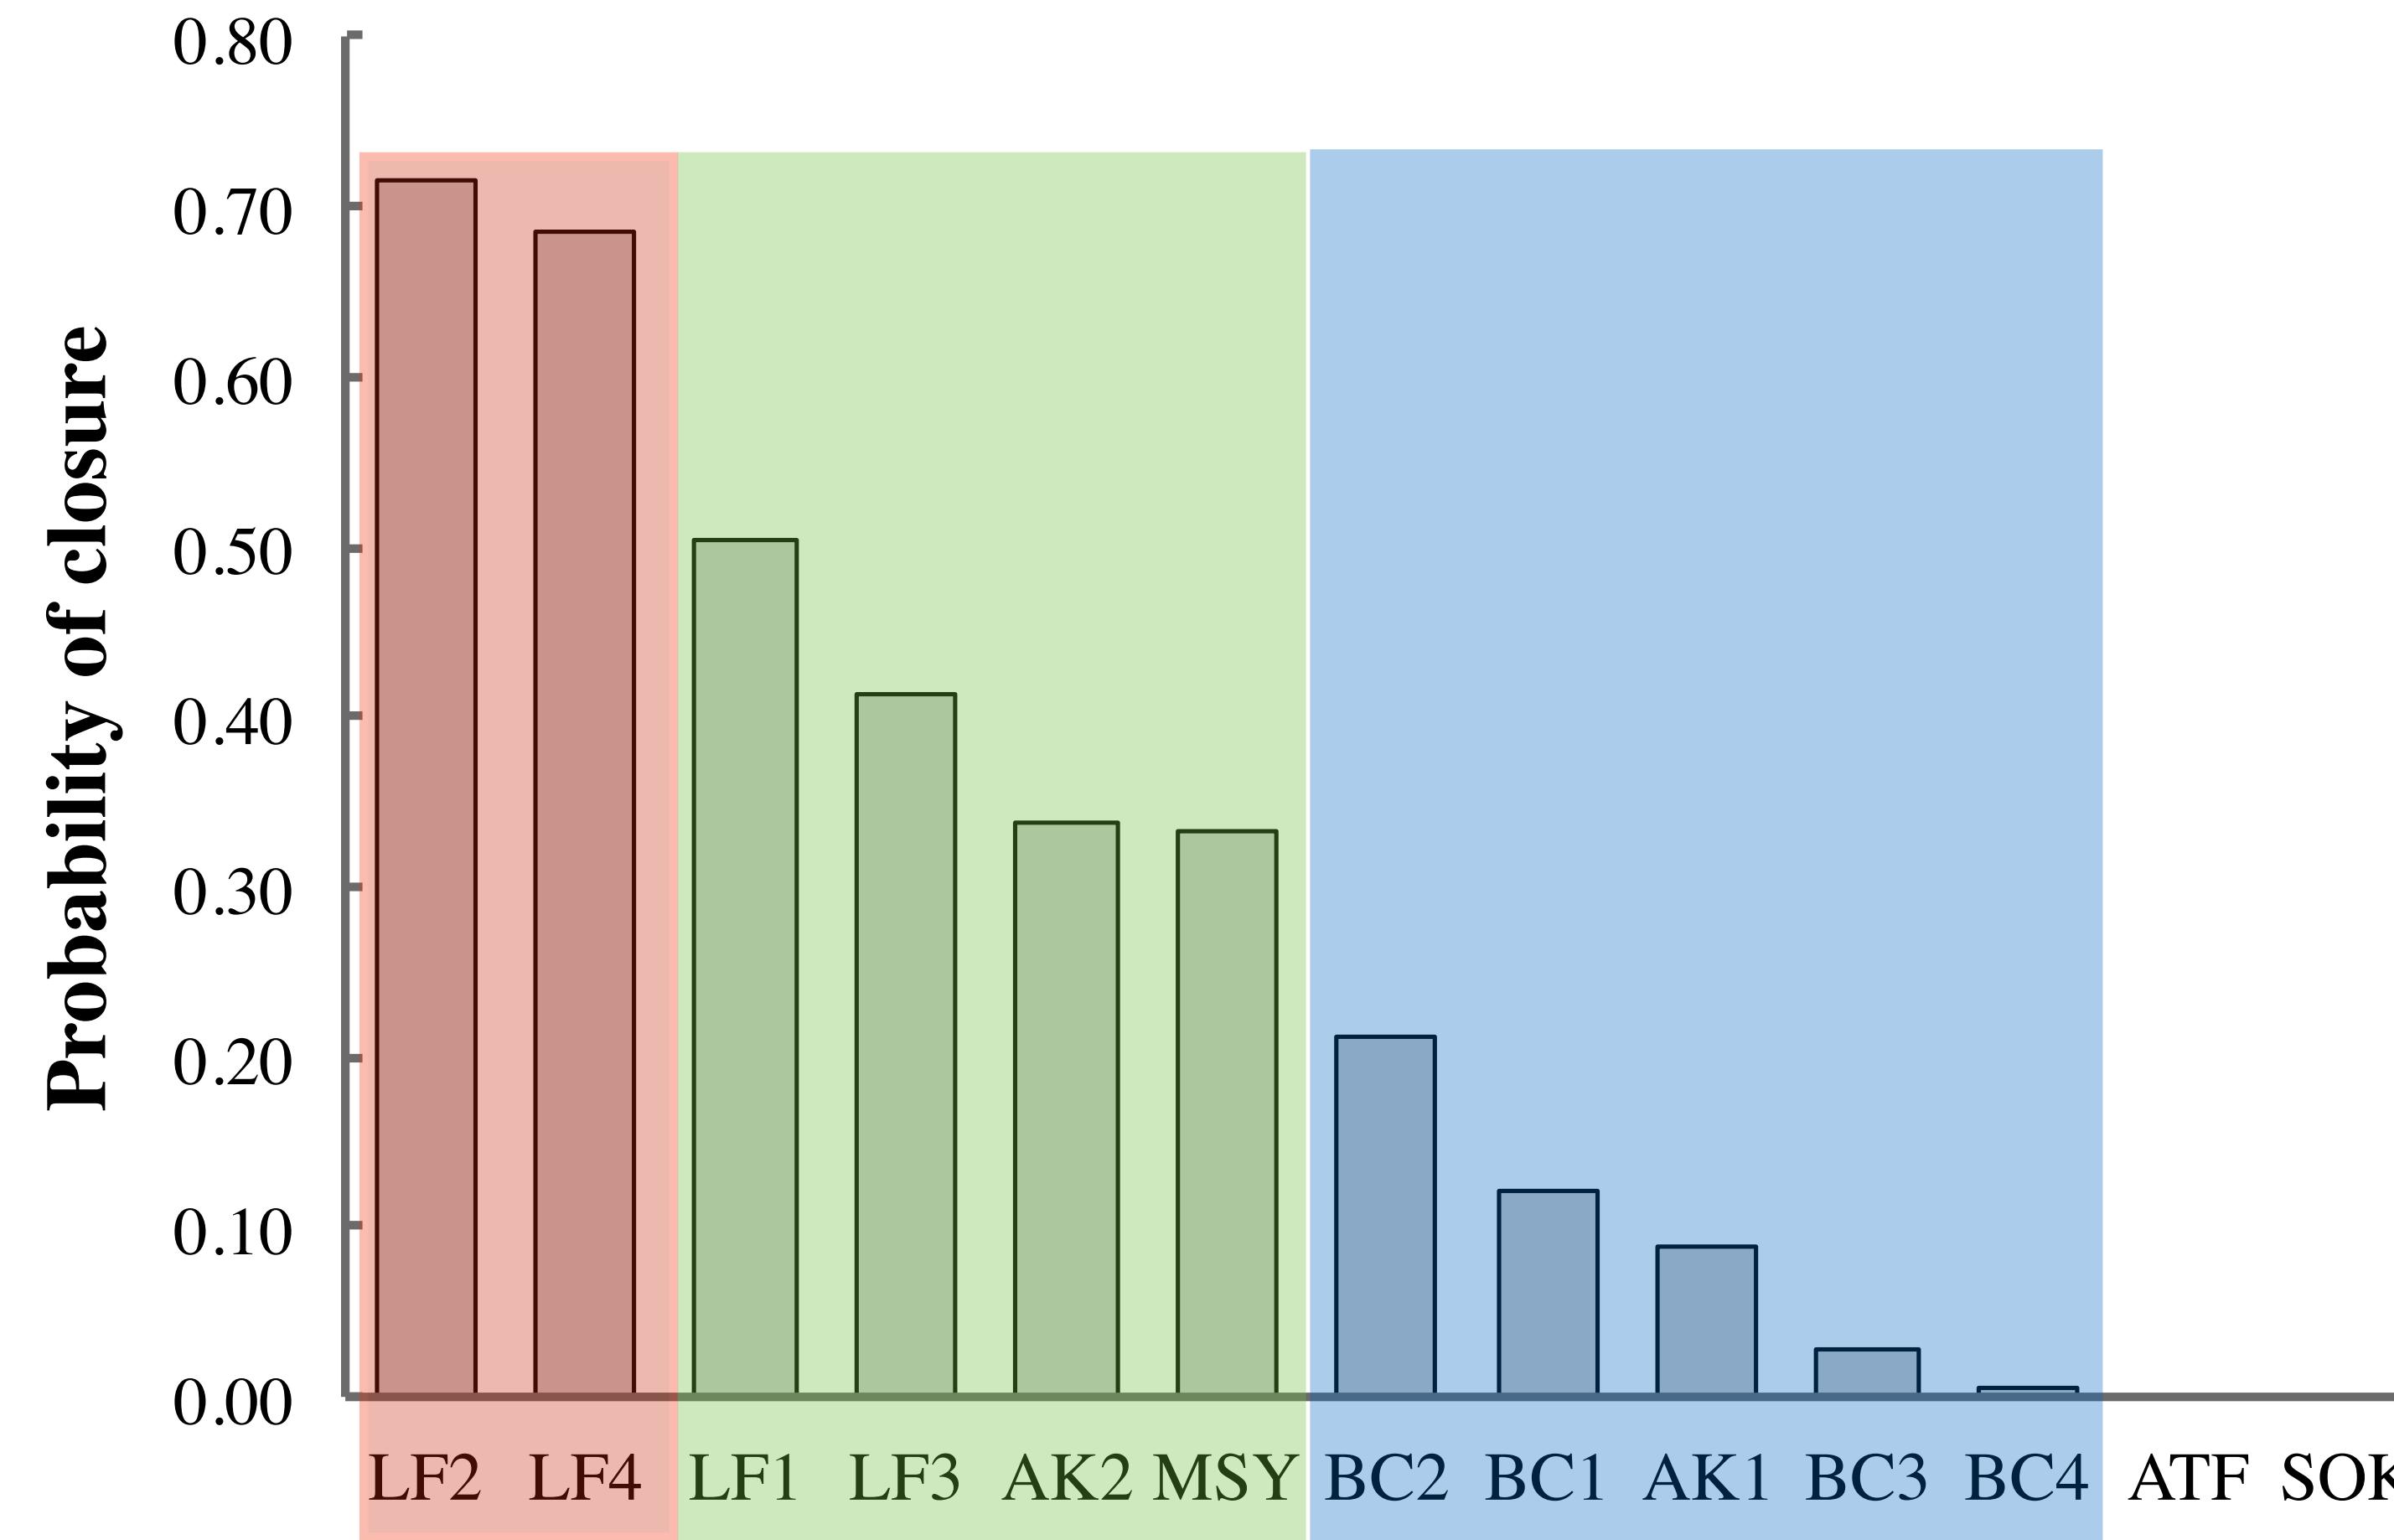

%

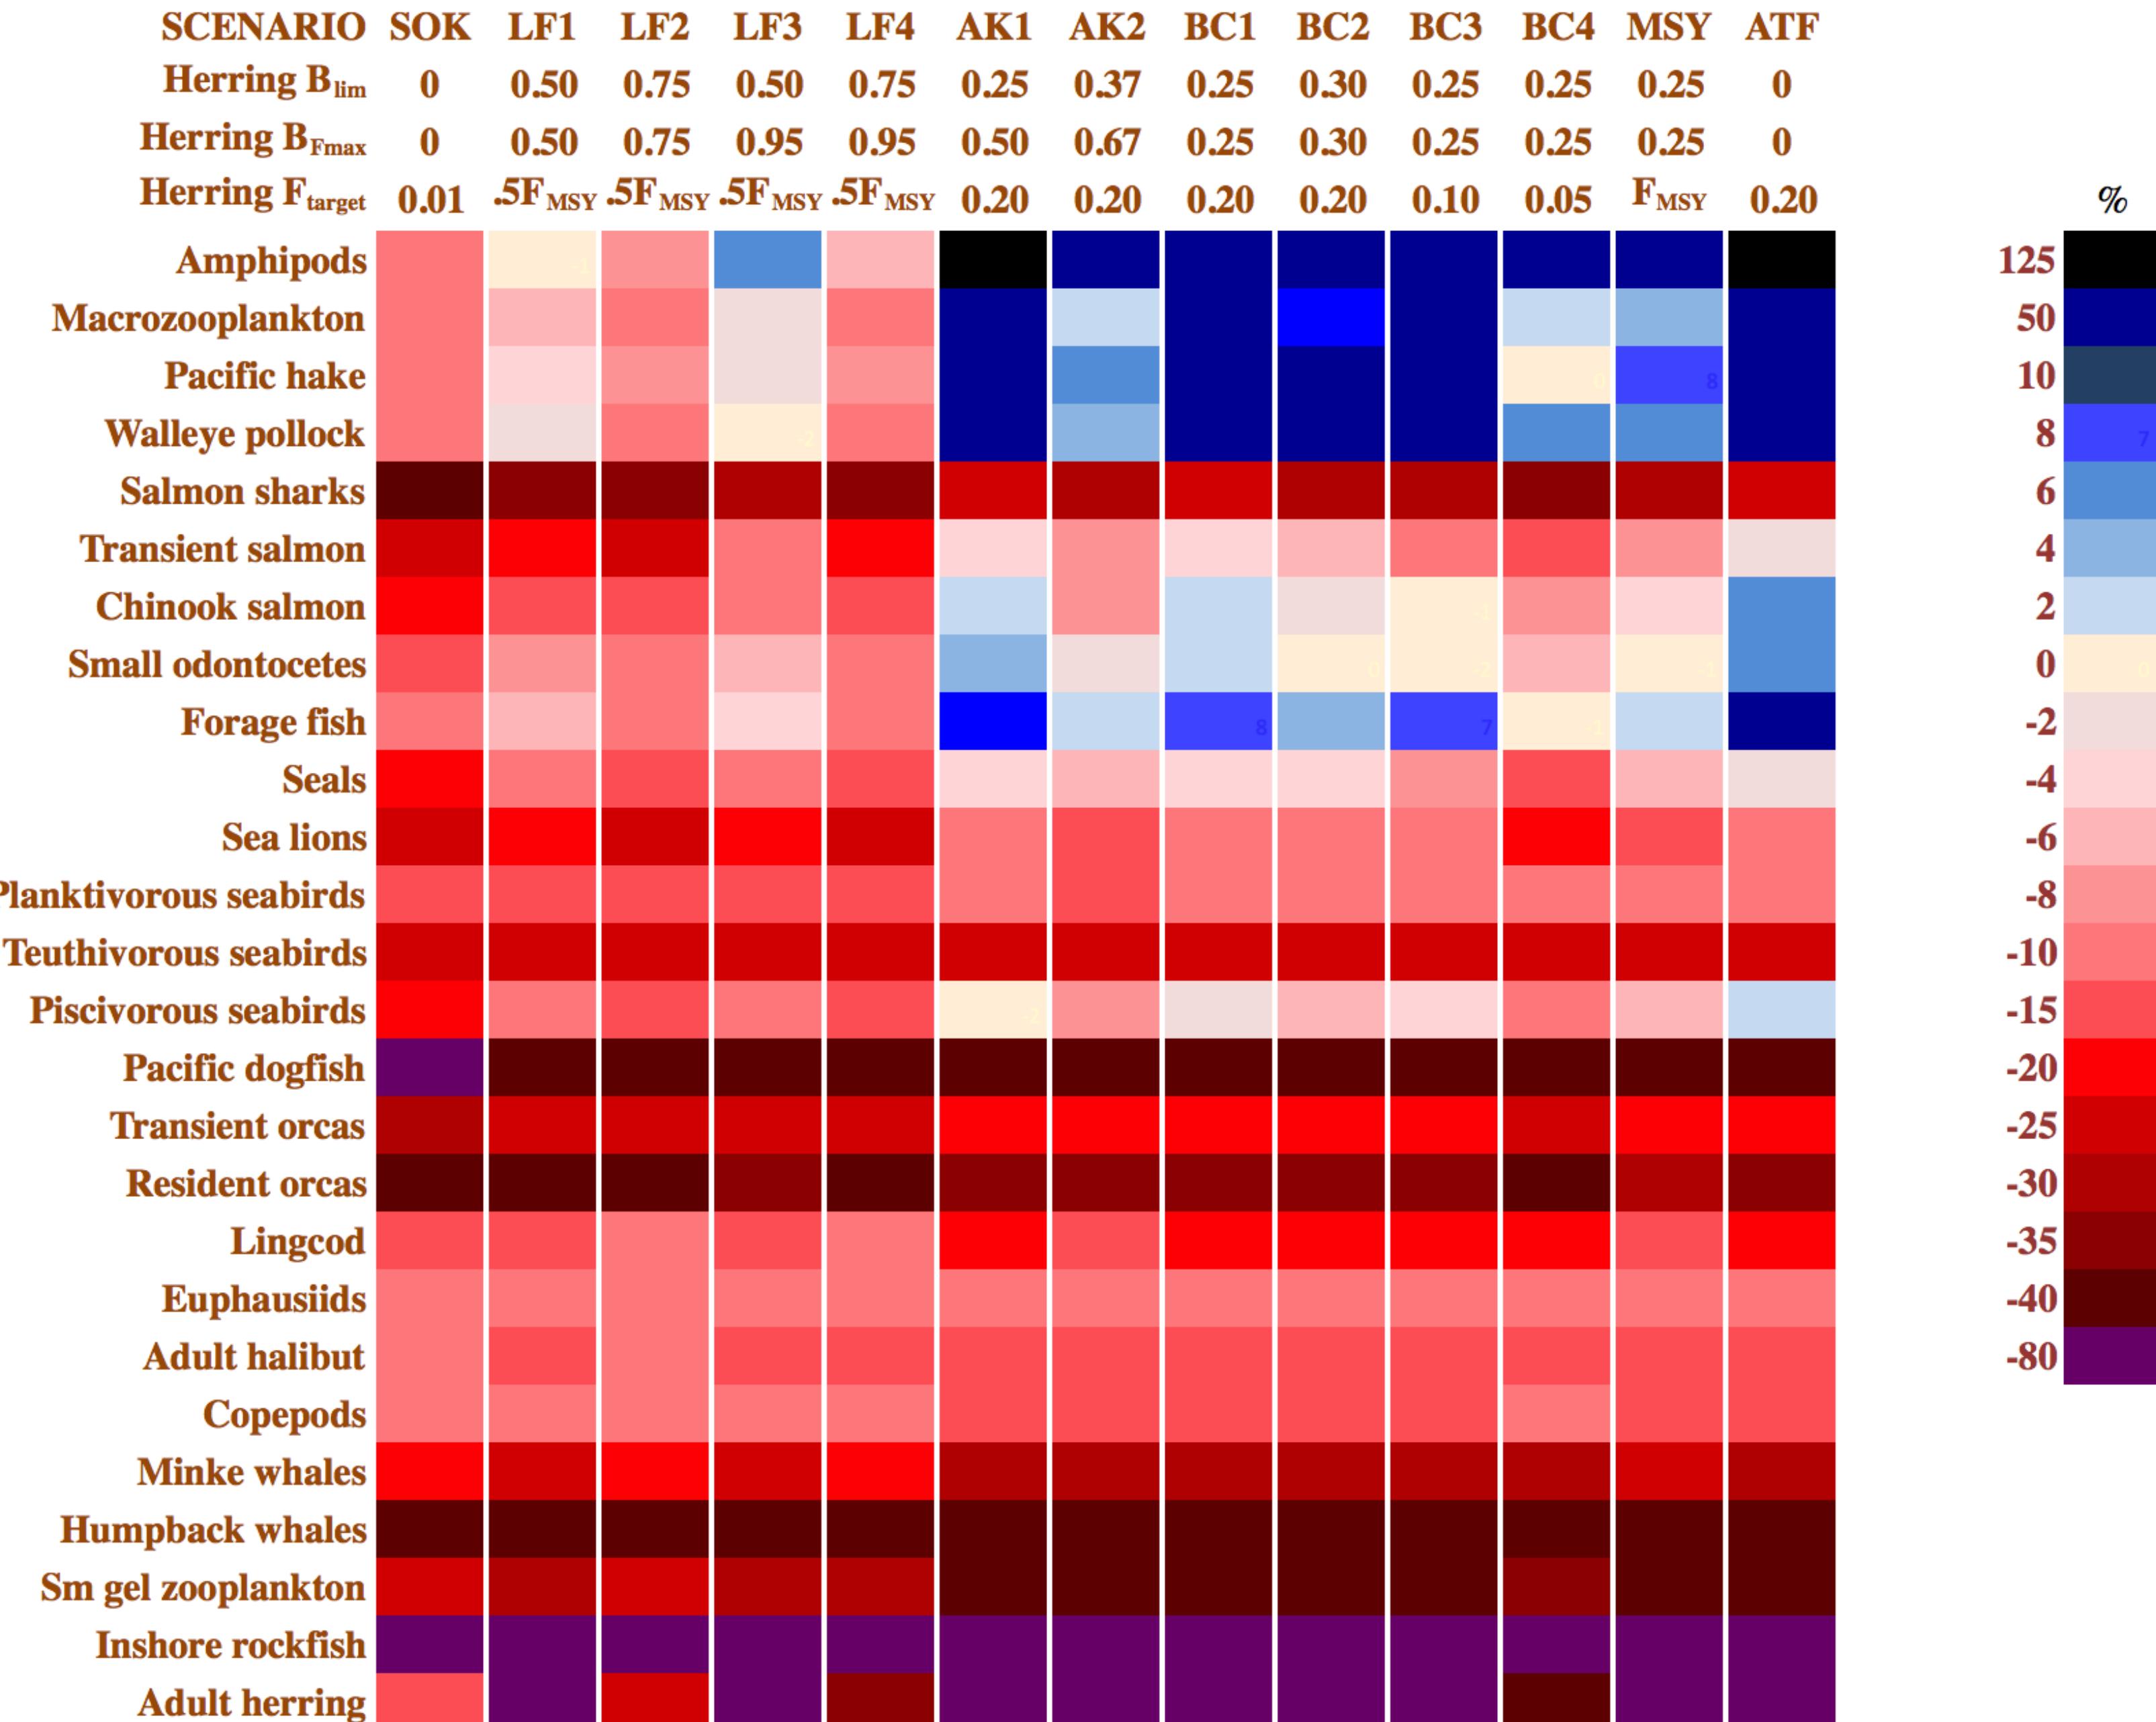

Median catch

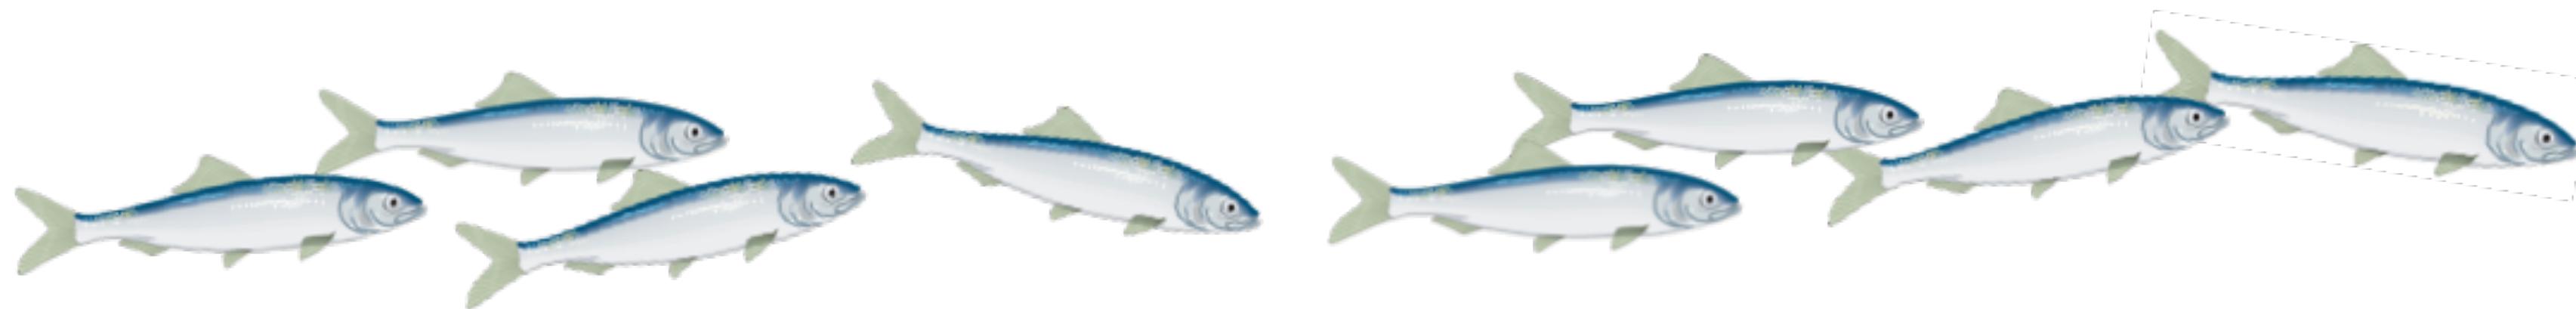

Closure probability

Conclusions

- ecosystem impacts of current strategies moderate
- tradeoff between ecological & socioeconomic goals
- strategy spectrum (historical & current, low F, EBFM)
- low predator biomass possible under all strategies

Pacific herring (*Clupea pallasii*) plays an important and multifaceted role in the Northeast Pacific as a forage fish in coastal ecosystems, target species for commercial fisheries, and culturally significant subsistence resource for coastal communities. This study comparatively evaluated herring fisheries management strategy performance relative to ecological and socioeconomic objectives. Management strategy evaluation employed a mass-balanced ecosystem operating model and accounted for parameter uncertainty, stock assessment error, and strategy implementation error through Monte Carlo resampling. Results revealed a notable trade-off between stable herring catches and high biomasses of herring and several predators. Herring biomass control point values influenced this trade-off more than harvest control rule form. All British Columbia and Alaska strategies yielded similar ecological and socioeconomic impacts relative to the unfished herring baseline. Precautionary strategies recommended for forage fish combined high ecosystem benefits and socioeconomic costs. Reducing fishing mortality fourfold within an existing strategy suggested a possible compromise solution to this trade-off. However, ecological impacts of all strategies were sensitive to operating model parameter uncertainty, stock assessment error, and strategy implementation error, with the potential for undesirable ecosystem states across all strategies. This study suggests trade-offs among management objectives should be considered in pursuing ecosystem-based fisheries management for forage fish.

Introduction

Pacific herring (*Clupea pallasii*) functions as an important forage fish and prey resource for numerous predators in the Northeast Pacific (Willson and Womble, 2006). These include seabirds (Schrumpf *et al.*, 2012; Bishop *et al.*, 2015; Sydeman *et al.*, 2017a; Drevier *et al.*, 2021) and commercial fish (Brodeur *et al.*, 2014; Osgood *et al.*, 2016), as well as numerous marine mammals, e.g. humpback whales (*Megaptera novaeangliae*; Boswell *et al.*, 2015; Moran *et al.*, 2018; Straley *et al.*, 2018) and Steller sea lions (*Eumetopias jubatus*; Gende and Sigler, 2006; Womble and Sigler, 2006; Sigler *et al.*, 2017).

The ecological role of Pacific herring is especially strong and taxonomically widespread during the spring spawning season, when both fish and roe become available to a diverse coastal predator guild (Willson and Womble, 2006). Thus, Schweigert *et al.*, (2010) describe herring as the primary forage fish in British Columbia waters, while Fox *et al.* (2015, 2018) categorize it as a foundation species (*sensu* Soulé *et al.*, 2003). Moreover, its high energy content relative to most other Northeast Pacific prey species (Perez, 1994; Anthony *et al.*, 2000; Vollenweider *et al.*, 2011) strengthens the importance of herring to its predators (Surma *et al.*, 2018a). Furthermore, many aboriginal, recreational, and commercial fisheries

A large humpback whale is breaching out of the ocean, its dark grey body and white pectoral fins visible against the greenish-blue water. Several white seabirds with dark wings are flying around the whale, some near its open mouth and others above it. The background shows more of the ocean with small waves.
