

# Phytoplankton Thin Layers Simulated by Large-Eddy Simulation

Ashley Brereton and Yign Noh

# Introduction

- ❖ Plankton live near the surface of the ocean.
- ❖ They are subjected to wind, wave and convection driven turbulence
- ❖ Despite turbulent mixing, spatial structures in the plankton are common in the surface waters
- ❖ One commonly observed structure is the phytoplankton *thin layer*
- ❖ We use a Large-eddy simulation model coupled to a simple biological model to investigate this phenomenon

# Thin layer observation, Mcmanus et. al (2003)

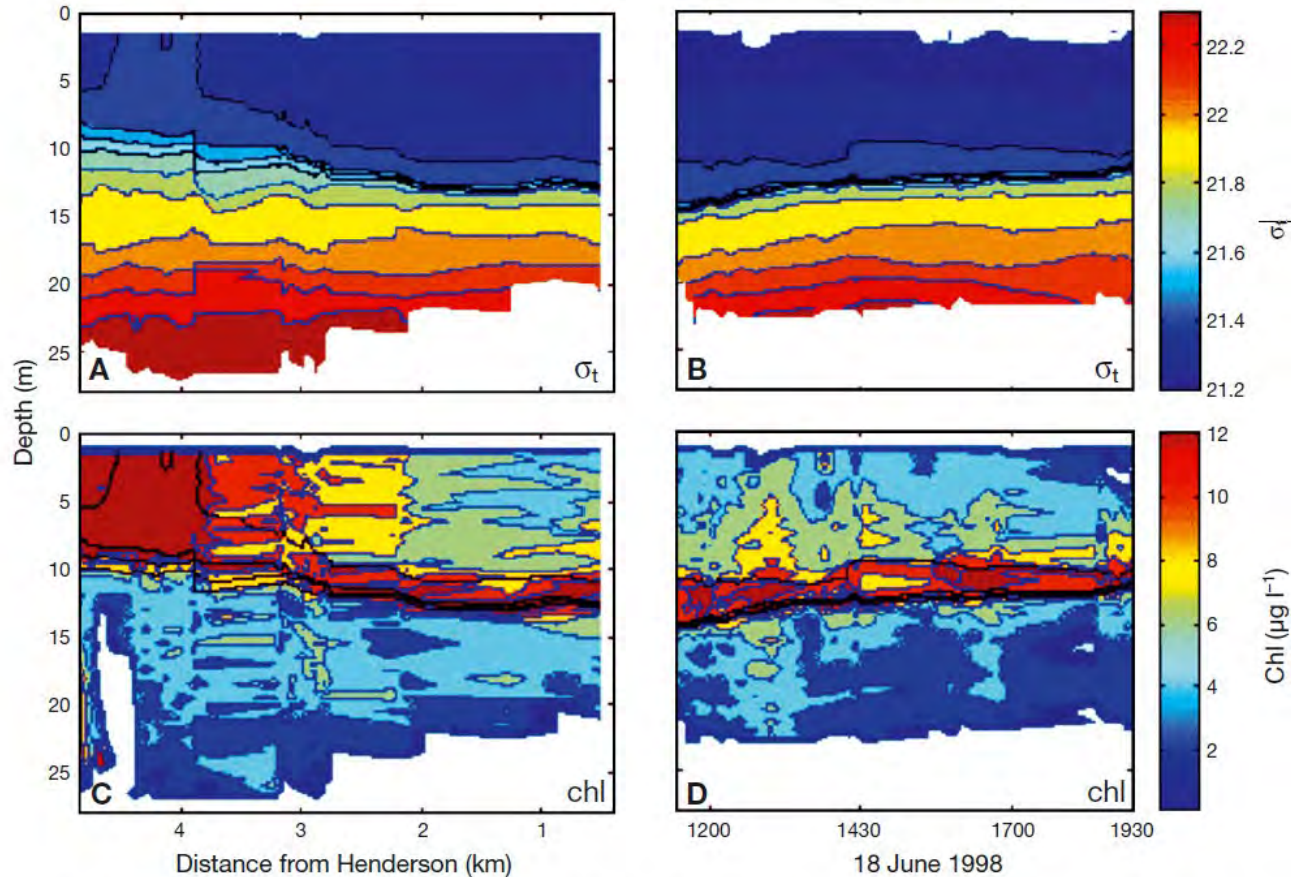

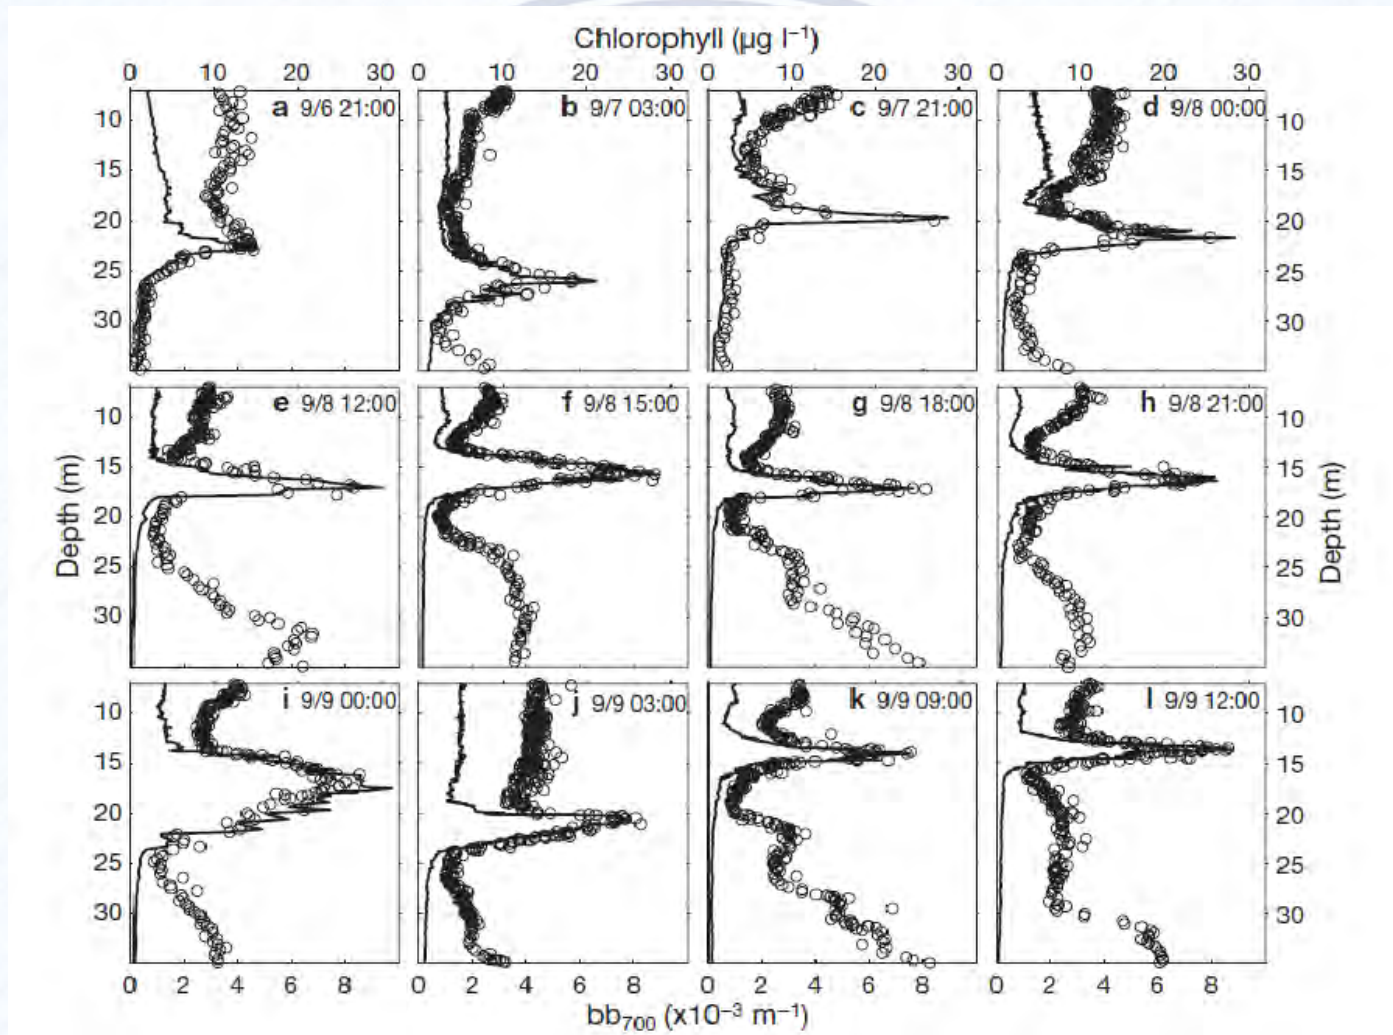

Fig. 3. (A)  $\sigma_t$  along transect from Rosario Point to RV 'Henderson'. (B) Time-series of  $\sigma_t$  measured from RV 'Henderson'.  $\sigma_t$  contours (21.4, 21.5, 21.6, 21.7) are drawn in black in (A) and (B). (C) Chlorophyll concentration ( $\mu\text{g l}^{-1}$ ) along transect from Rosario to RV 'Henderson'. (D) Chlorophyll concentration ( $\mu\text{g l}^{-1}$ ) at RV 'Henderson'. Chlorophyll concentration estimated from  $(a_p 676 - a_p 650)/0.012$  (where  $a_p$  = phytoplankton absorption); red = chlorophyll concentrations  $> 12 \mu\text{g l}^{-1}$ . 'Third Love' was next to RV 'Henderson' at approximately 14:30 h on June 18; non-plotted values at bottom of graphs are due to sediments for which  $a_p 676 - a_p 650 < 0$

# Dekshenieks et. al (2001)

ness from 0.12 m to 3.61 m (mean 1.20 m). Roughly 44% of layers were <1 m in thickness, and 80% of

and strength of the pycnocline. Roughly 62% of all thin layers were at the base of the pycnocline (Fig. 6a). This

to  $0.45 \text{ m}^{-1}$  (mean  $1.33 \text{ m}^{-1}$ ) (Table 1, Fig. 4c). About 72% of the thin layers had absorption intensities that ranged from  $0.25$  to  $1.5 \text{ m}^{-1}$  (Fig. 4c).

There is a second class of thin optical layer adjacent to the bottom. These bottom layers were found in 31 (26%) of the profiles. They ranged from 0.23 to 3.11 m in thickness (mean 1.30 m). Bottom layer intensities ranged from  $0.26$  to  $2.24 \text{ m}^{-1}$  (mean  $0.80 \text{ m}^{-1}$ ). Thus, bottom layers had similar thickness to and slightly lower intensities than water column thin layers. We do not include bottom layers in these

(> $2.3 \text{ m}^{-1}$ ) occurred at lower wind speeds (< $4 \text{ m s}^{-1}$ ). In East Sound, surface waters from 2 to 10 m are strongly

tain higher layer intensities.

## Thin phytoplankton layers and the pycnocline

Thin layer depth was closely associated with depth and strength of the pycnocline. Roughly 62% of all thin layers were at the base of the pycnocline (Fig. 6a). This pattern was observed on all cruises, but was strongest in May. Approximately 9% of thin layers were distributed

# Model description

❖ Physical model: Large-Eddy Simulation (LES)

❖ PALM 5.0

$$\frac{\partial u}{\partial t} + u \cdot \nabla u + f \times u = -\frac{\nabla p}{\rho_0} + \nabla \cdot \nu_t \nabla u - \frac{\rho g}{\rho_0}$$

$$\nabla \cdot u = 0$$

❖ Filtered Navier-Stokes equations

❖ Fully 3-dimensional

❖ Turbulence resolving

# Model description

- ❖ Biological model: Nutrient-Phytoplankton model (NP)
- ❖ Phytoplankton are treated as Lagrangian particles
- ❖ Each particle is representative of a number of phytoplankton cells, denoted by a weighting factor  $W$ .
- ❖ This weighting factor varies with the net growth rate of the phytoplankton i.e.

- $W_{t+\delta t} = W_t \times (1 + \delta t \times \text{Net growth rate})$

$$\text{Net growth rate} = \overbrace{G e^{Kz} \frac{N}{N_0}}^{\text{growth}} - \underbrace{\tilde{D}}_{\text{death}}$$

# Model description

- ❖ Biological model: Nutrient-Phytoplankton model (NP)
- ❖ Nutrient is treated as an Eulerian scalar

$$\frac{\partial N}{\partial t} + \mathbf{u} \cdot \nabla N = \nabla \cdot D_t \nabla N - P \times \text{Net growth rate}$$

# Model setup

# Model setup

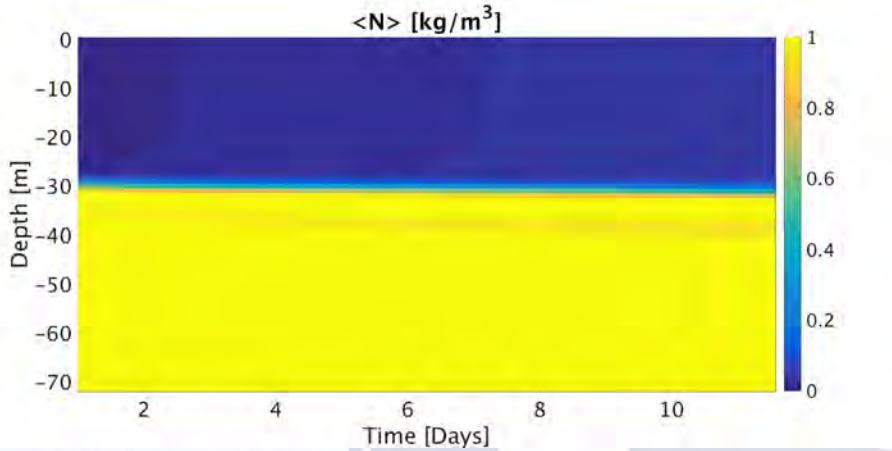

- ❖ Domain size:  $L_x = L_y = 300\text{m}$   $L_z = 80\text{m}$
- ❖ Domain resolution:  $\delta x = \delta y = \delta z = 1\text{m}$
- ❖ Period horizontal boundary conditions
- ❖ Wind forcing:  $4\text{ms}^{-1} - 12\text{ms}^{-1}$
- ❖ Initial surface mixed layer: 30m
- ❖ Initial stratification: 0.1 Kelvin/m
- ❖ Initial Nutrient:  $10\mu\text{mol l}^{-1}$
- ❖ Amount of particles: 9,000,000
- ❖ Phytoplankton size: 50 $\mu\text{m}$

# Simulation design

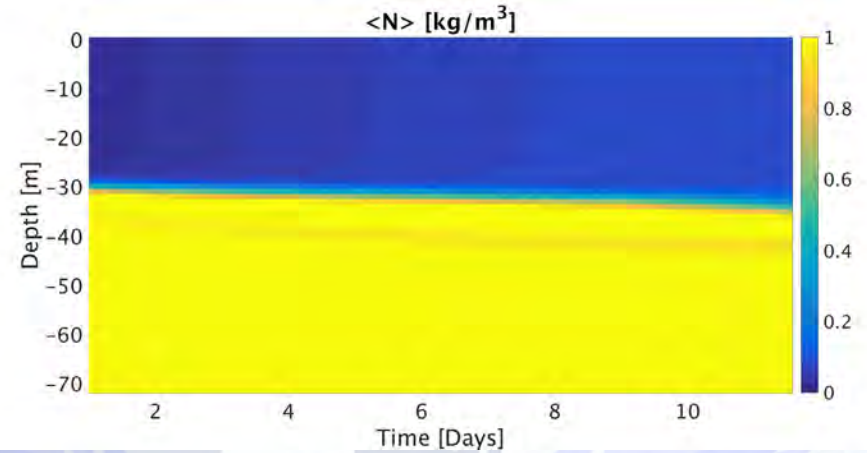

# Nutrient response to wind

Low wind ( $4ms^{-1}$ )

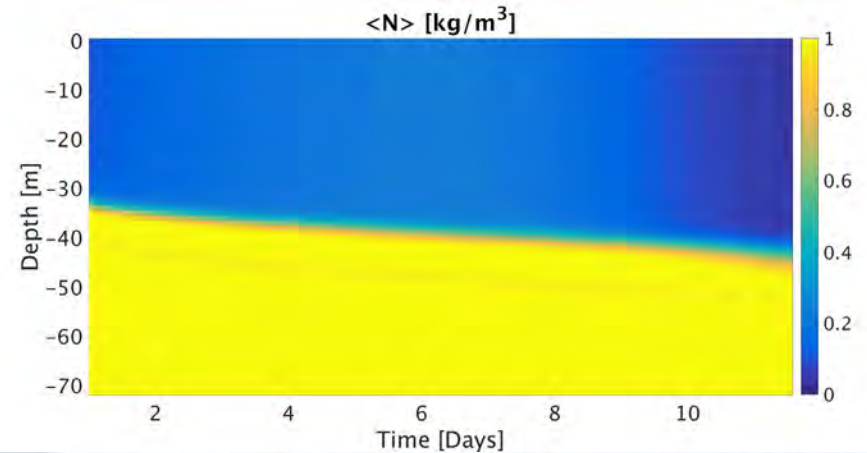

( $6ms^{-1}$ )

( $8ms^{-1}$ )

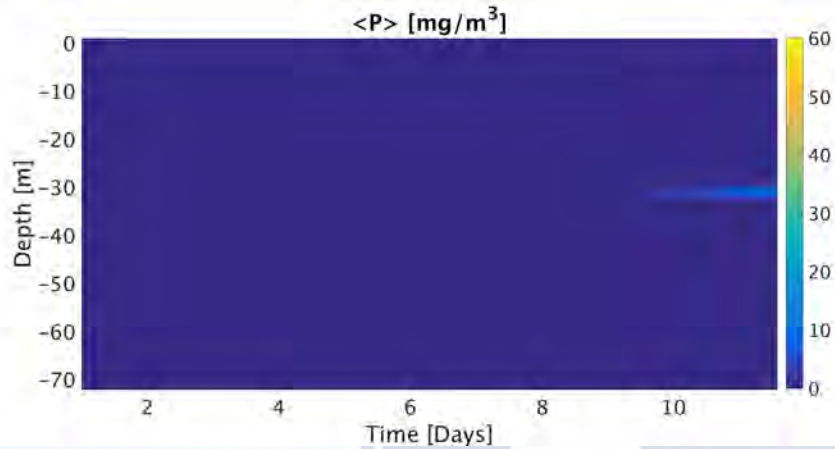

High wind ( $10ms^{-1}$ )

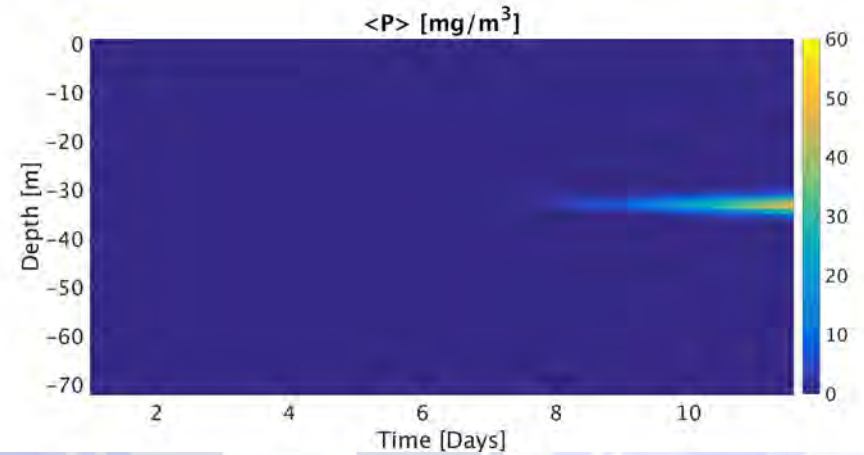

# Plankton response to wind

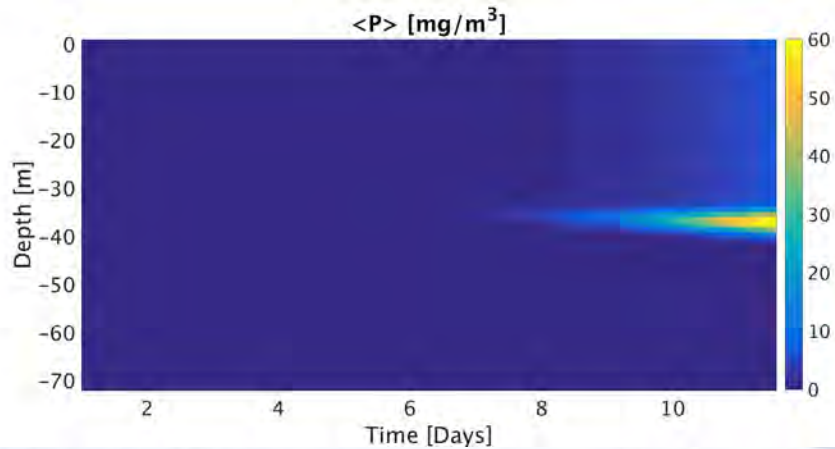

Low wind ( $4\text{ms}^{-1}$ )

( $6\text{ms}^{-1}$ )

( $8\text{ms}^{-1}$ )

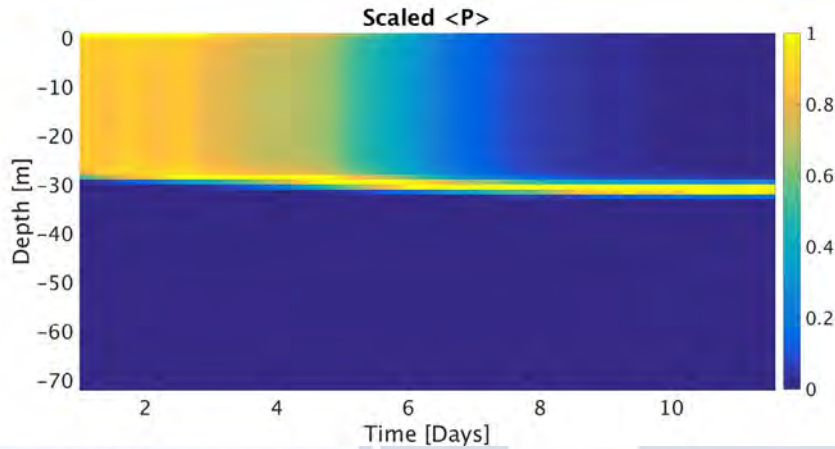

High wind ( $10\text{ms}^{-1}$ )

# Plankton (Scaled by max) response to wind

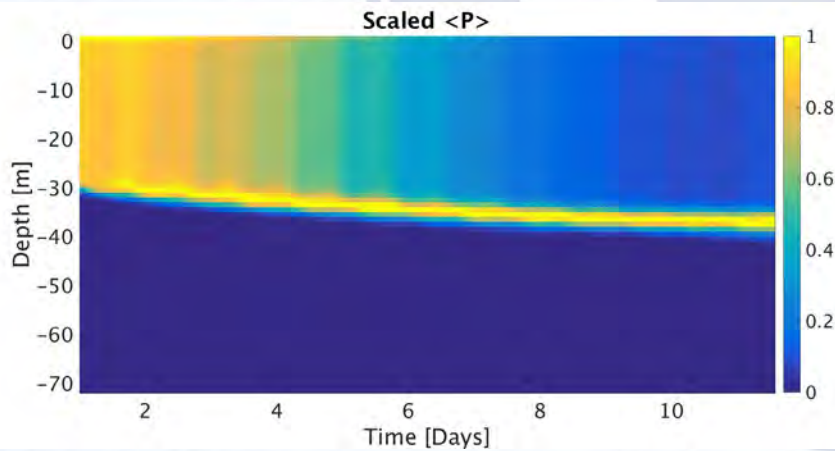

Low wind ( $4ms^{-1}$ )

( $6ms^{-1}$ )

( $8ms^{-1}$ )

High wind ( $10ms^{-1}$ )

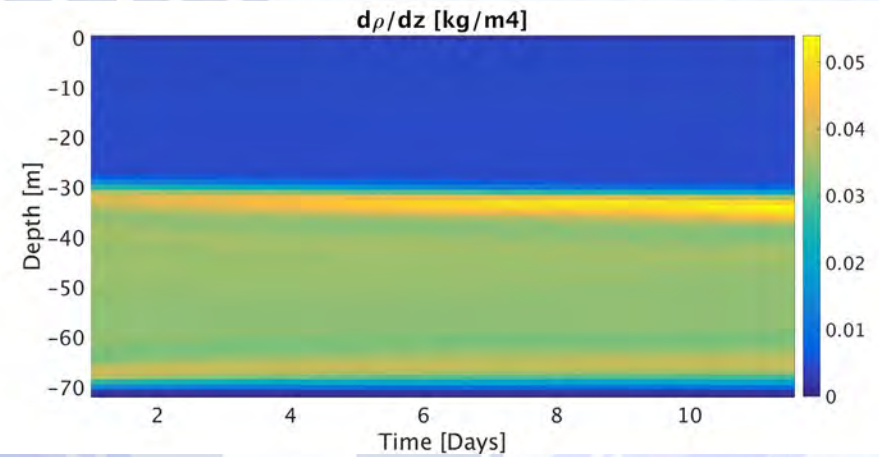

# Stratification

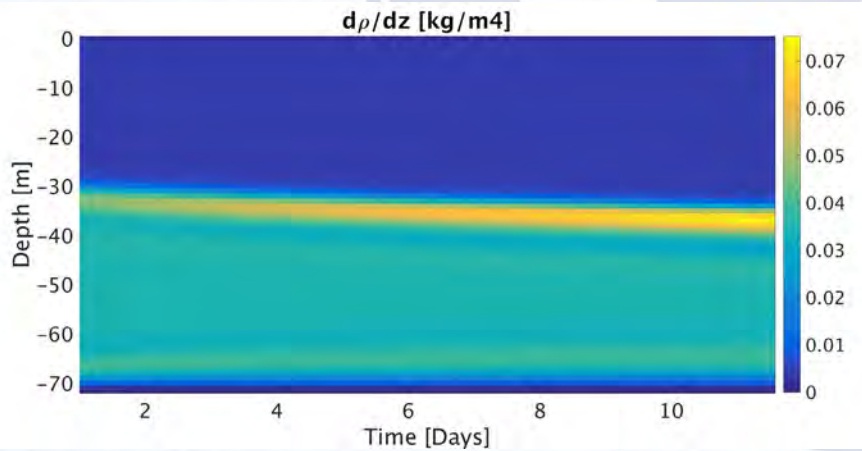

Low wind ( $4ms^{-1}$ )

( $6ms^{-1}$ )

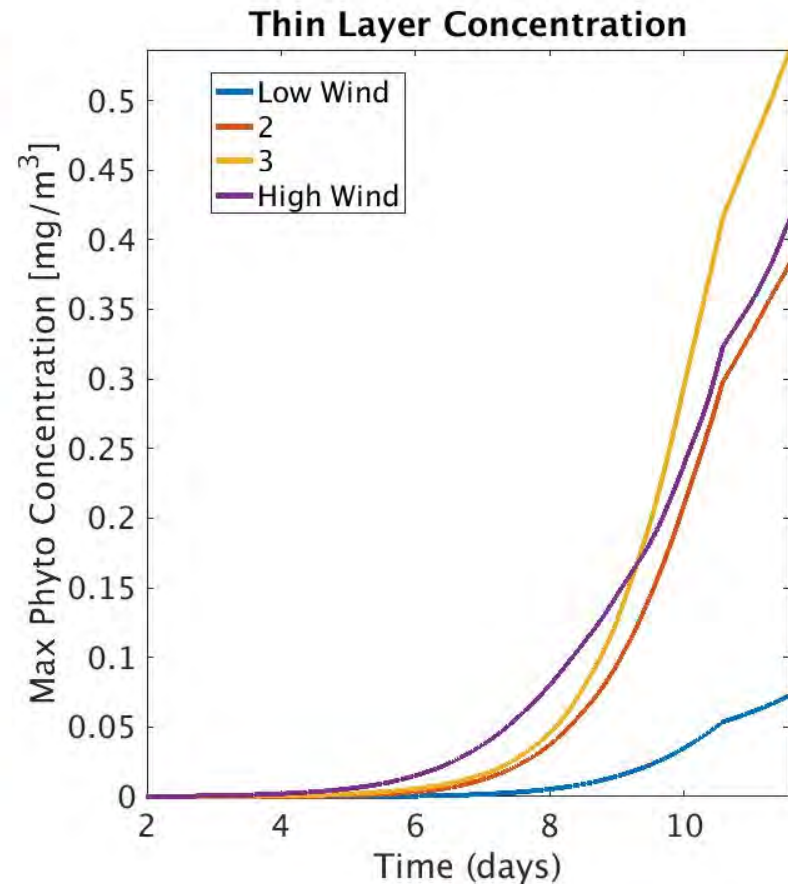

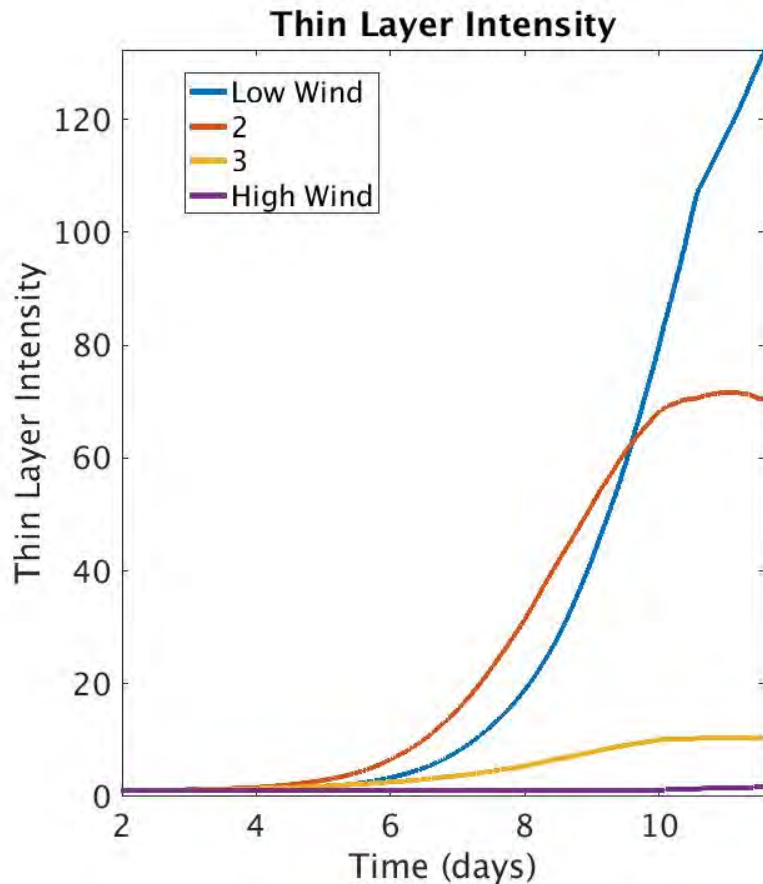

( $8ms^{-1}$ )

High wind ( $10ms^{-1}$ )

# DCM Intensity

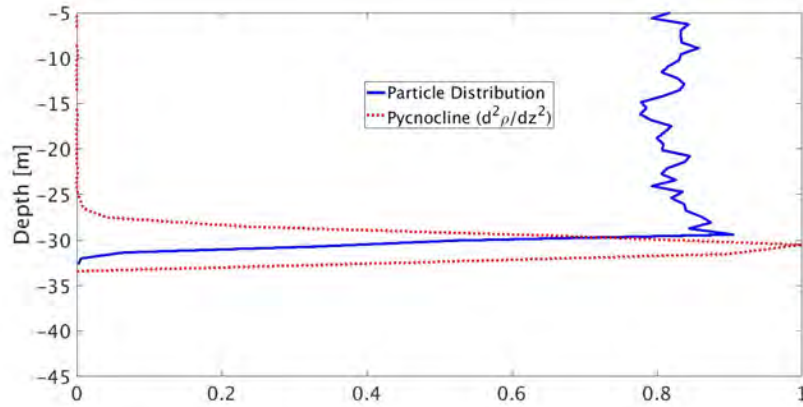

$$\text{Thin Layer Intensity} = \frac{\text{Maximum Phytoplankton concentration}}{\text{Surface Phytoplankton concentration}}$$

# Quick Summary I

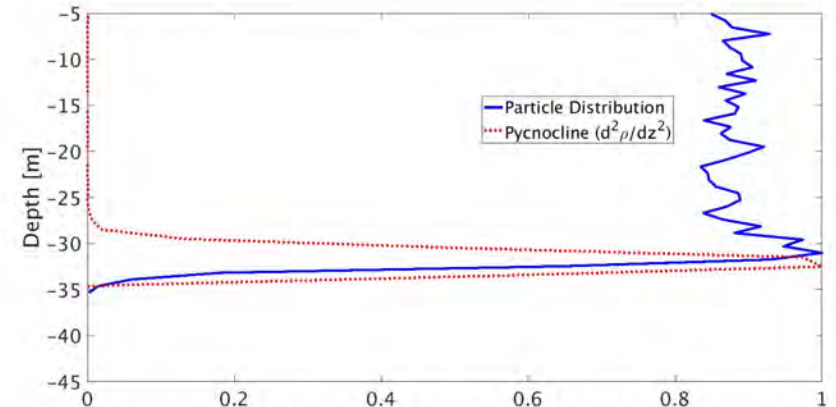

- ❖ Thin layers form at the pycnocline
- ❖ Low wind = Low concentration in thin layer
- ❖ High wind = Low thin layer intensity

# Phytoplankton (particle) injection

Low wind ( $4ms^{-1}$ )

( $6ms^{-1}$ )

( $8ms^{-1}$ )

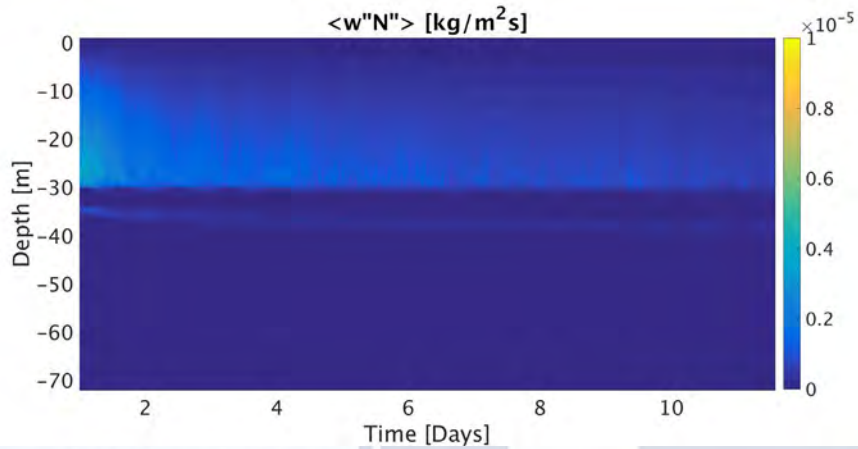

High wind ( $10ms^{-1}$ )

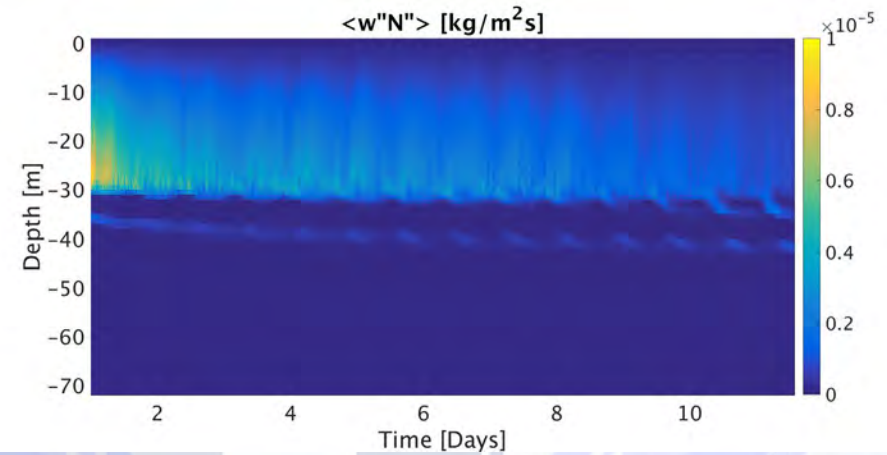

# Nutrient Entrainment $\langle N'w' \rangle$

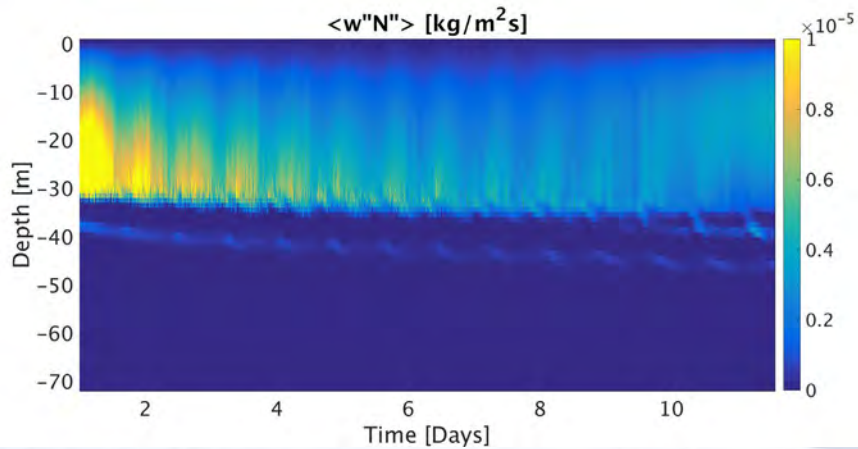

Low wind ( $4ms^{-1}$ )

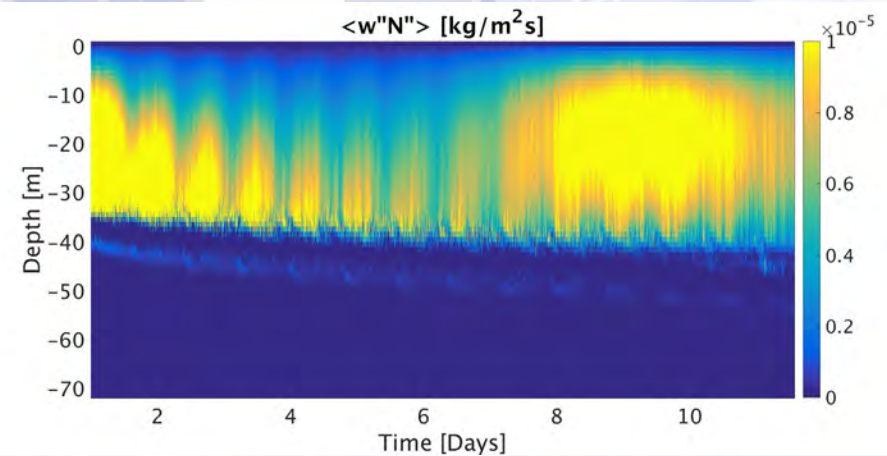

( $6ms^{-1}$ )

( $8ms^{-1}$ )

High wind ( $10ms^{-1}$ )

# Quick Summary II

- ❖ Low wind = Small amount of particles injected into pycnocline
- ❖ High wind = Lots of nutrient entrainment into surface water

# Proposed Mechanisms, Durham and Stocker (2012)

# Dynamical consideration

- ❖ A thin layer should form if the timescale of growth is much larger than the timescale of vertical mixing.

$$\frac{\partial \langle P \rangle}{\partial t} = \underbrace{-\frac{\partial}{\partial z} \langle wP \rangle}_{\text{Mixing}} + \underbrace{Ge^{-Kz} \langle PN \rangle - D \langle P \rangle}_{\text{Growth}}$$

$$\langle F \rangle = \frac{1}{XY} \int_0^y \int_0^x F \, dx \, dy$$

- ❖ Which term is dominant?

# Dynamics breakdown – Plankton

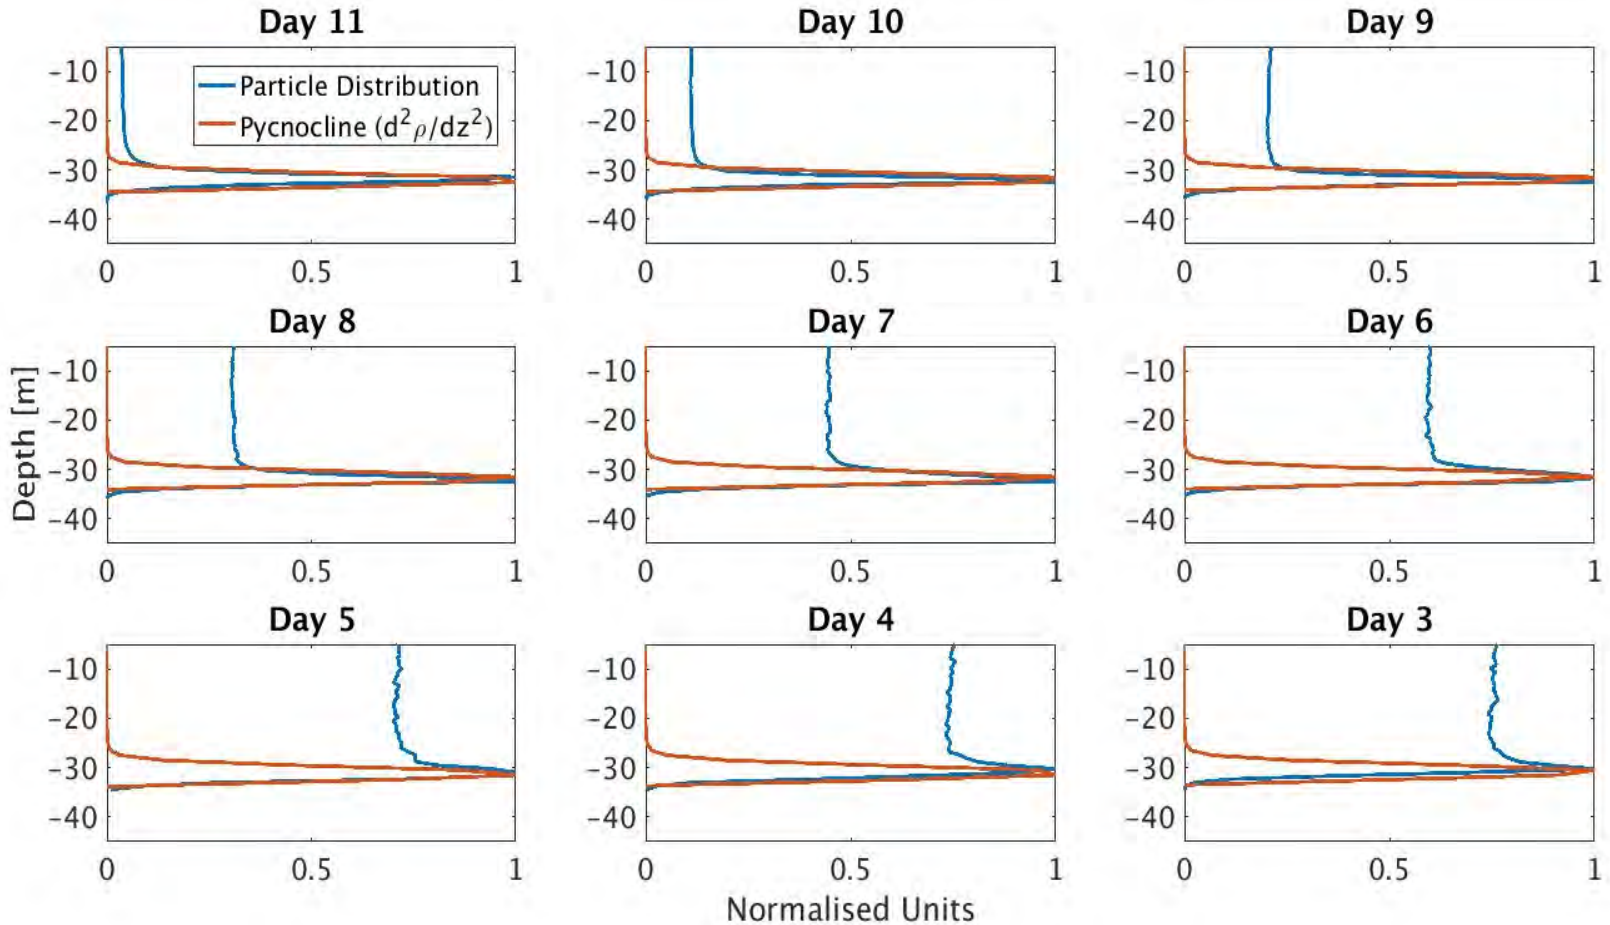

$$\frac{\partial \langle P \rangle}{\partial t} = \underbrace{-\frac{\partial}{\partial z} \langle wP \rangle}_{\text{Mixing}} + \underbrace{Ge^{-Kz} \langle PN \rangle - D \langle P \rangle}_{\text{Phytoplankton Growth rate}}$$

# Quick Summary III

- ❖ Results show that in-situ growth is taking place
- ❖ Timescale of biological growth outweighs timescale of vertical mixing
- ❖ **Why do they grow here?**
- ❖ As we are using particles, we can trace the journey of the thin layer plankton back through time.

# Thin layer particles at the pycnocline

# Conclusions

- ❖ We demonstrated thin layer formation with simple passive particles.
- ❖ Thin layers always occur in the pycnocline
- ❖ Model results reveal patterns observed in the field
- ❖ Once particles reach the pycnocline, they are trapped for a sustained period, giving them time to feed in the nutrient rich water.
- ❖ The thin layer is strongest when a compromising level of wind is realised.
  - If wind is too weak, less particles are injected into the pycnocline
  - If wind is too strong, too many nutrients are brought to the surface to feed the competing surface plankton
