Fisheries and Oceans
Canada

Key messages

1. Decrease in ecosystem consideration from conceptual hypothesis (46%) stage to management advice (27%)
2. A combination of qualitative and quantitative approaches for accounting for ecosystem considerations is required
3. Frequent re-evaluation of hypotheses and metrics is required under changing climate and ecosystem status.
4. Critical gap: Evaluation of the performance of management decisions with and without ecosystem considerations
5. Critical gap: Seasonal to decadal ocean projections at appropriate spatial scales are required

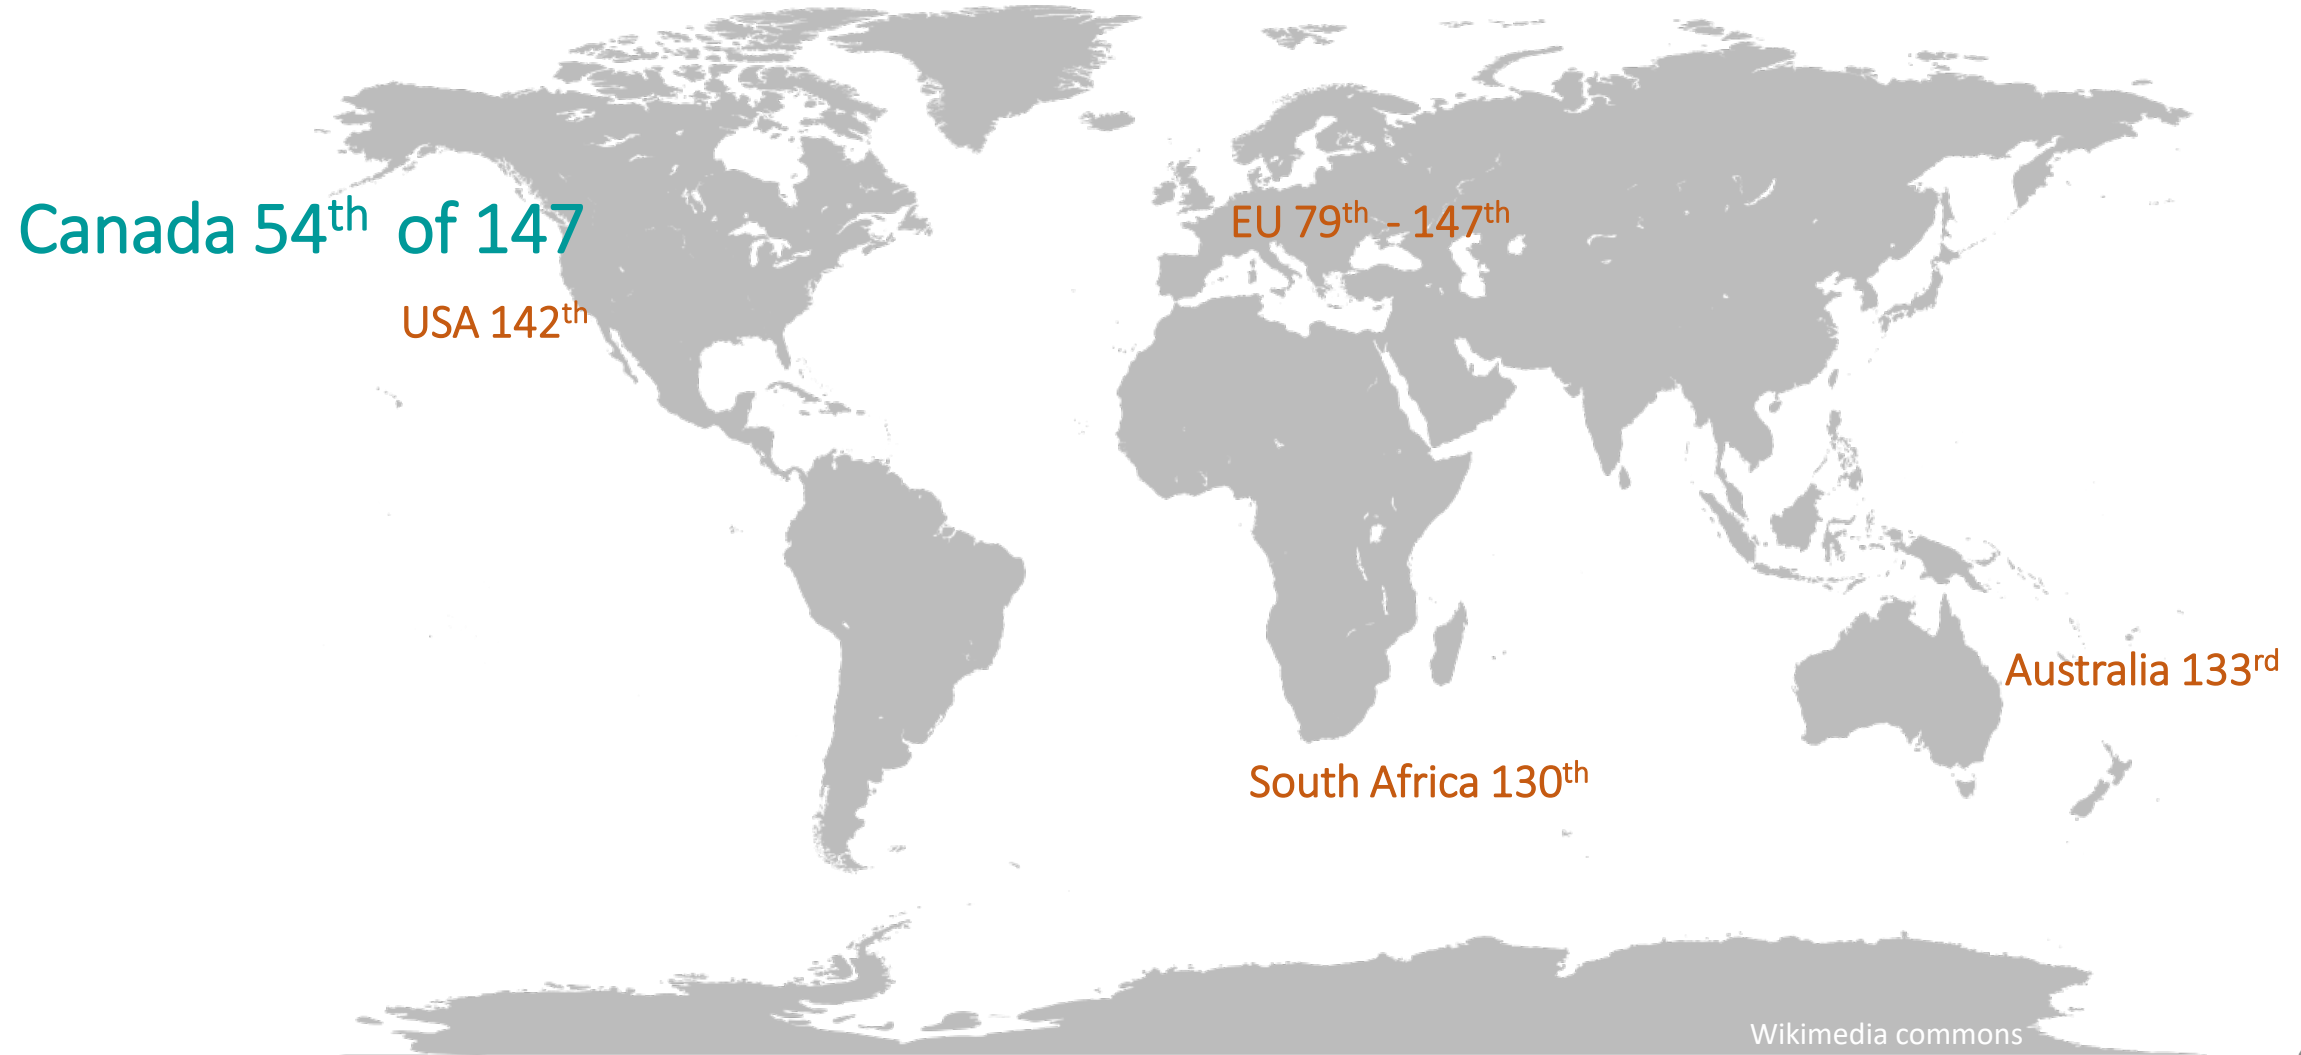

Ecosystem Approach to Fisheries Management

Fisheries and Oceans
Canada

Countries with marine fisheries most vulnerable to climate change

Climate impacts

Trophic structure and spatial distribution

Temperature, wind, turbulence

patterns

Benthic habitat

CO₂ and O₂: acidification

Objective

To what extent do Canadian fish stock assessments apply environmental information to models, assessments, or advice to Resource Management?

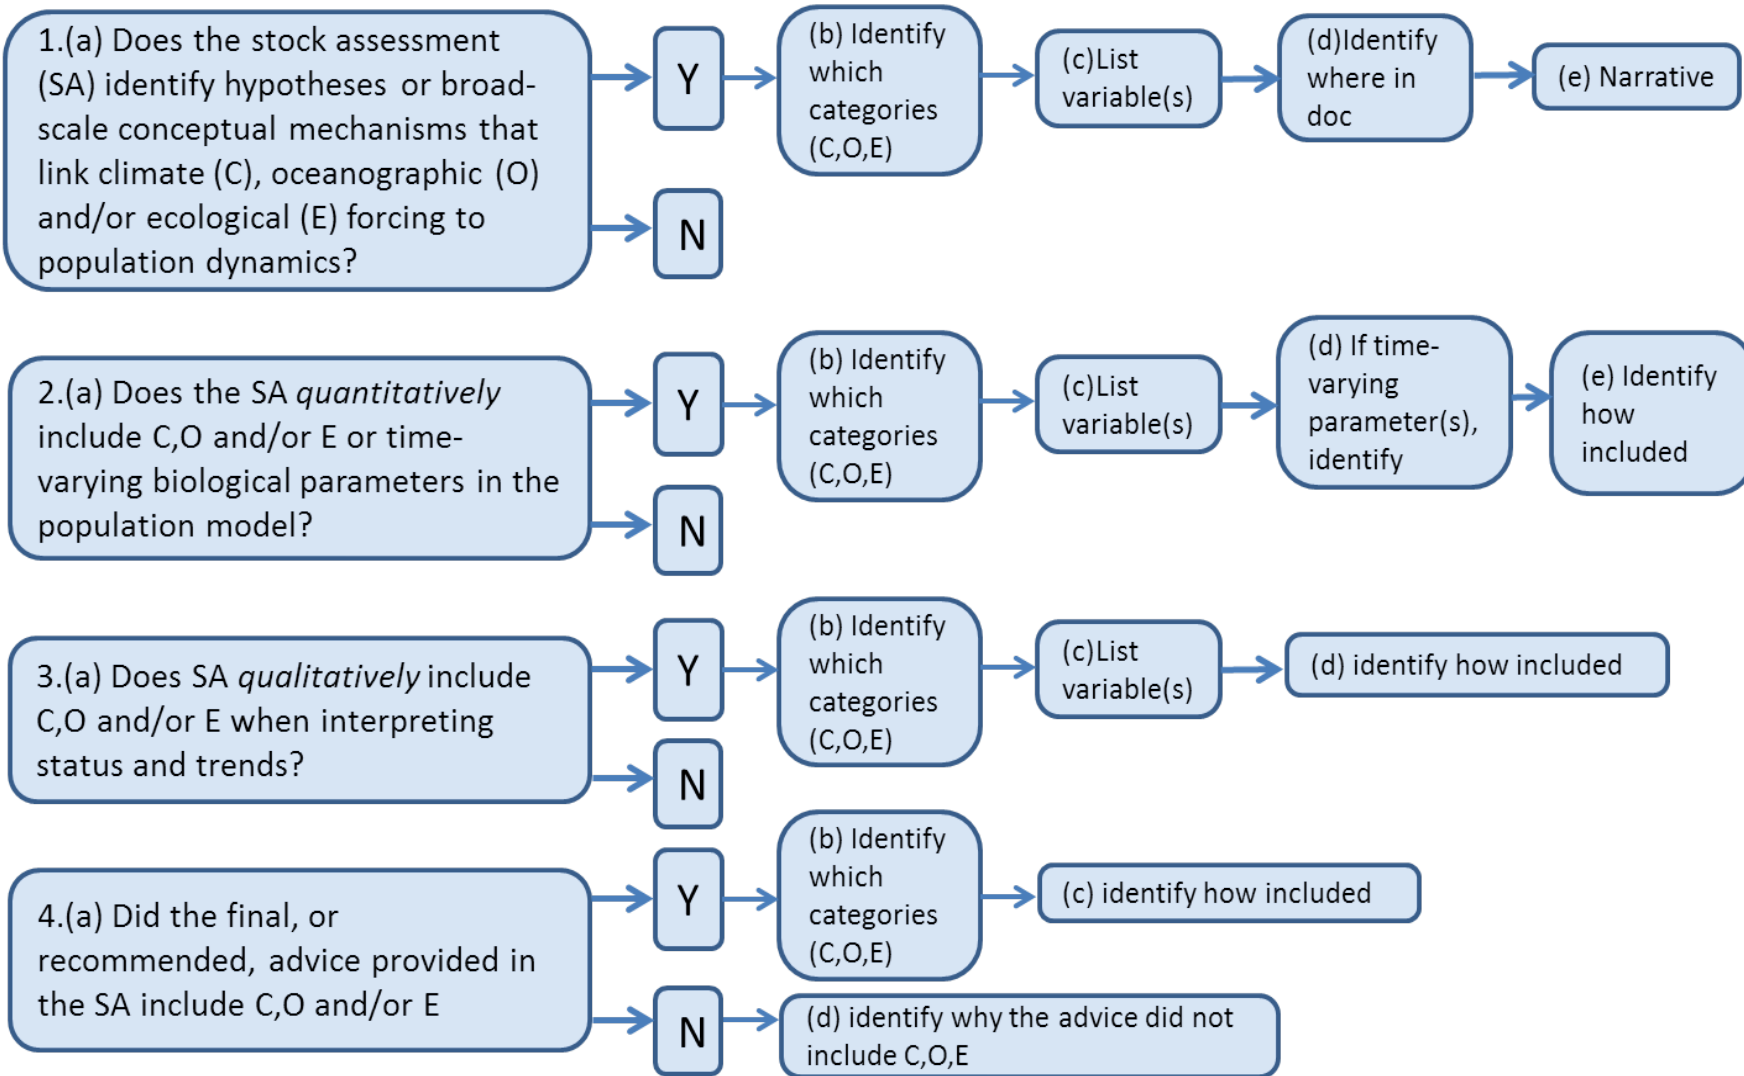

- 178 recent stock advisory documents, by taxonomic group and region
- Evaluated general conceptual knowledge, methods for consideration, and whether advice was informed by environmental variables

Environmental Drivers

- Climate (**C**) drivers: long-term (multi-year) variations and trends in regional or large-scale atmospheric processes
- Oceanographic (**O**) drivers: associated with climatic variability but include short-term and/or regional variability
- Ecological (**E**) drivers: broad range of ecosystem features, e.g., trophic interactions and habitat requirements

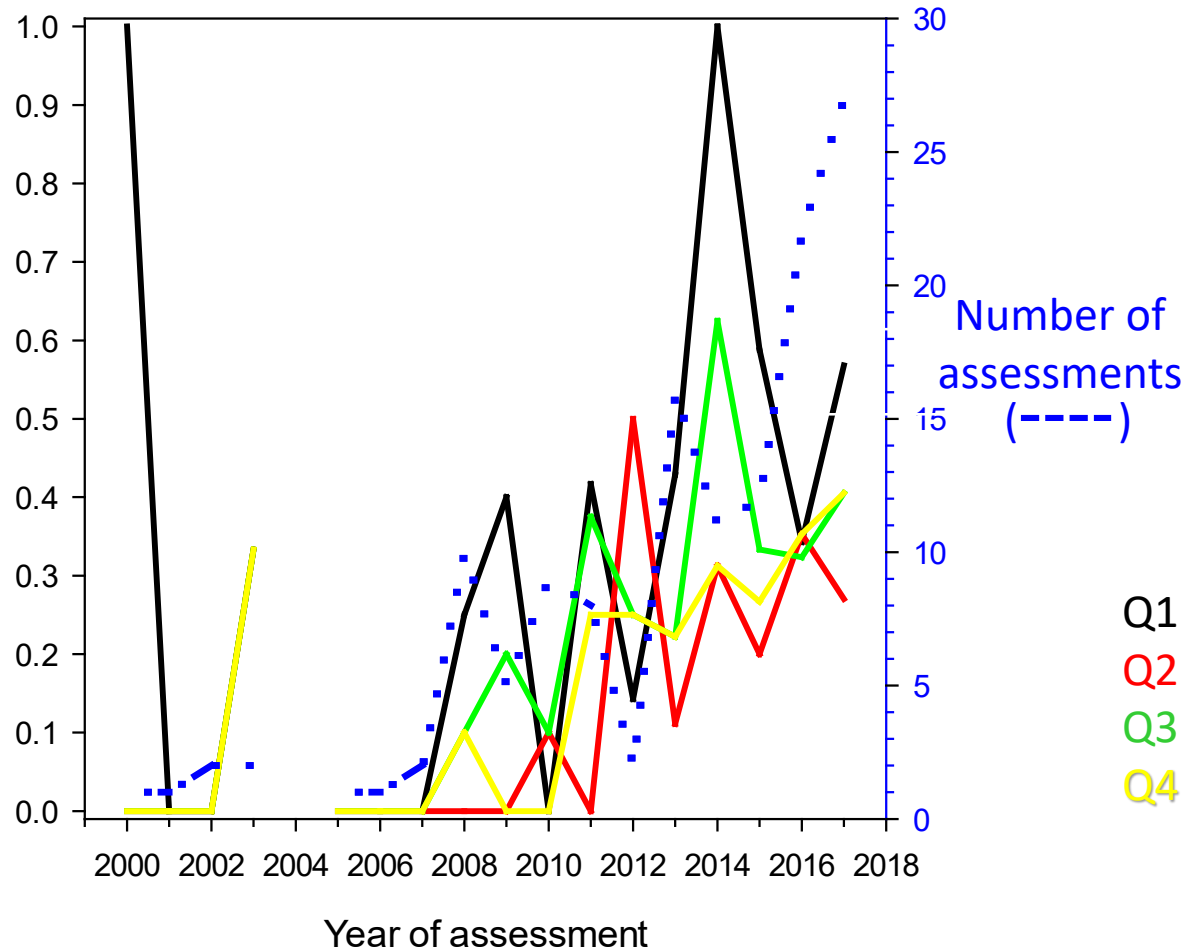

Questions used to conduct Inventory of Climate, Oceanographic, Ecological information in Canadian Stock Assessments

Results

Proportion of assessments that include environmental (C,O,E) variables

- Q1 Broad-scale processes or hypotheses
- Q2 Quantitatively
- Q3 Quality to explain trends
- Q4 In advice to resource management

Results

Proportion of assessments that include environmental (C,O,E) variables

Results

| Taxa | Concept | Quantitative | Qualitative | Advice |
|--------------|---------|--------------|-------------|--------|
| Anadromous | 0.58 | 0.65 | 0.46 | 0.58 |
| Pelagic | 0.50 | 0.14 | 0.43 | 0.36 |
| Invertebrate | 0.53 | 0.17 | 0.36 | 0.26 |
| Groundfish | 0.44 | 0.15 | 0.22 | 0.15 |
| Mammal | 0.21 | 0.11 | 0.21 | 0.26 |
| Elasmobranch | 0.14 | 0.00 | 0.14 | 0.00 |

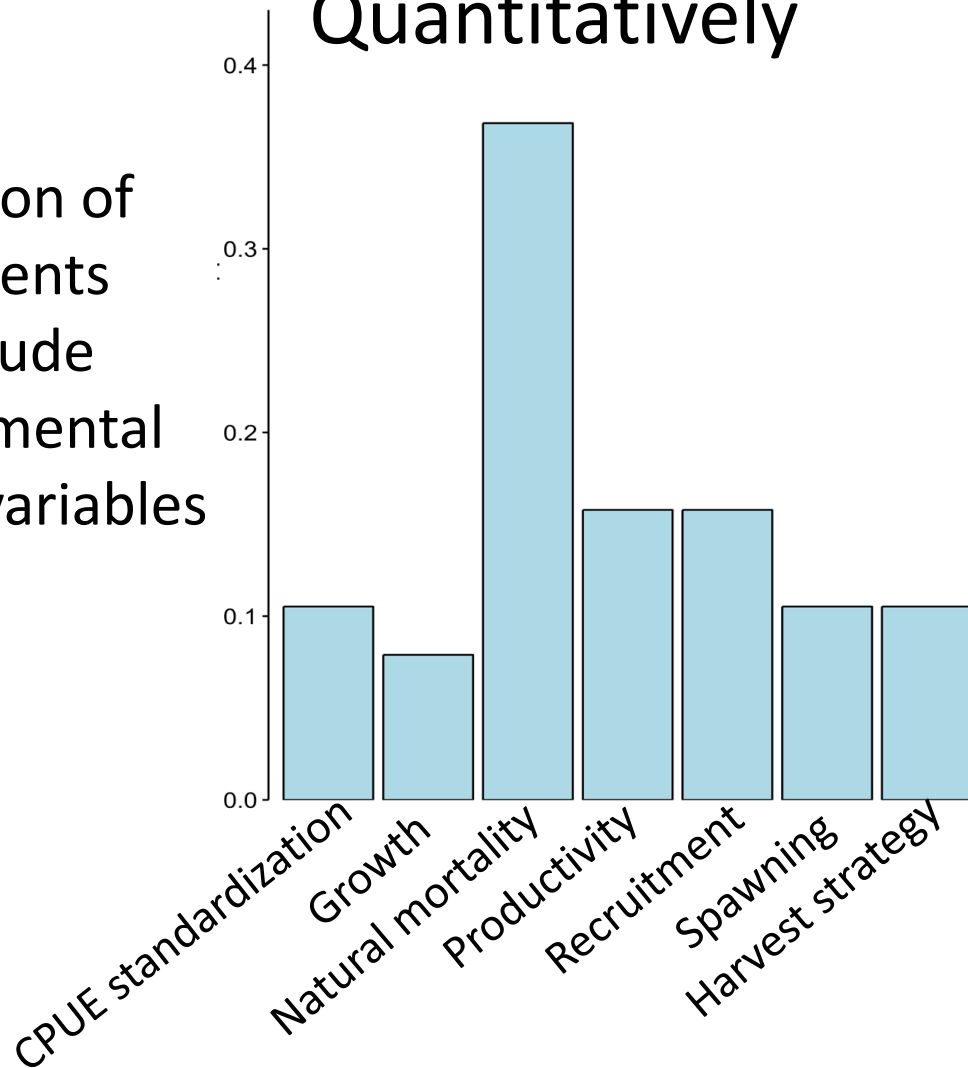

Proportion of assessments that include environmental (C,O,E) variables

Approaches for including in assessment

Quantitatively

Proportion of assessments that include environmental (C,O,E) variables

Qualitatively

- Explain trends (temporal and spatial)
- Explain anomalies
- Forecast based on categorical indices (e.g., stoplights)
- Account for uncertainties

Approaches for including in advice

- Inform implementation of **harvest control rule, HCR** (90% of cases)
 - via time-varying parameters in models (31%)
- Provide expectation for future potential
- **Sensitivity** of HCR performance to uncertainty in climate impacts
- Occasionally used **qualitatively to recommend precaution** in choice of TAC or exploitation rates
- Gap: ¼ of these **did not include hypothesized mechanisms**, being based on exploratory analyses

When not considered in advice, why not?

- Data limitations (45%)
- Lack of mechanisms (39%)
- Climate dwarfed by other factors (17%)

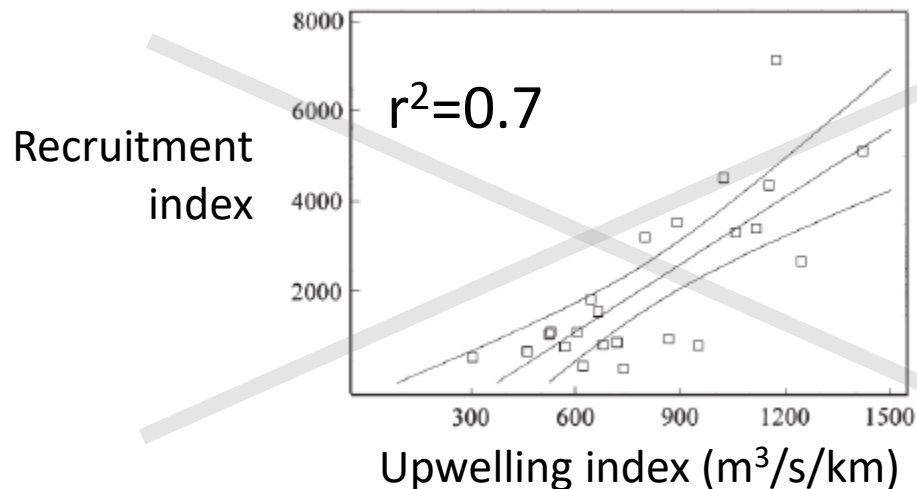

International examples

US: Pacific Sardine, Arrowtooth flounder, Pink salmon...

Australia: Rock Lobster. Bluefin Tuna...

Europe: Blue Whiting, Bay of Biscay Anchovy...

Bay of Biscay Anchovy: correlation between upwelling and recruitment included in advice to management late 1990s, until 2000/2001 when relationship broke down

(Borja et al. 1996;1998; ICES 2001; 2005)

Ecosystem Status Reports
A synthesis of the status and trends of an ecosystem

Ecosystem Status Reports (ESRs) synthesize indicators to provide an overview of the status, trends, and possible future conditions of ecosystem components. The third step in NOAA's Integrated Ecosystem Assessment approach of assessing the ecosystem often results in Ecosystem Status Reports. ESRs are produced for resource managers and stakeholders such as Fishery Management Councils (FMCs), National Marine Sanctuaries, state governments and other marine resource management organizations. By providing system-wide context and highlighting the status and trends of indicators, ESRs are instrumental in facilitating ecosystem-based management for our regional marine resource management partners.

Ecosystem Status Reports provide managers:

- An integrated view of socio-economic, biological, and physical

Regional Ecosystem Status Reports:

- CALIFORNIA CURRENT
- GULF OF MEXICO
- NORTHEAST
- WEST HAWAII
- ALASKA

Key points

- Decrease in ecosystem consideration from conceptual stage to advice
- A combination of qualitative and quantitative approaches is likely required
- Frequent re-evaluation of hypotheses and metrics is required under changing climate and ecosystem status.

Critical gaps

- Evaluation of the management performance with and without ecosystem considerations (Management Strategy Evaluation and retrospectively)
- Seasonal to decadal ocean projections
- Impacts on Arctic species

National Ecosystem Approach to Fisheries
Management Working Group (DFO 2019-2023)

Recommendation: Climate and Fisheries Strategy

Countries already developed / are developing strategies are:

- USA
- Australia
- ICES
- South Africa
- ICCAT

Summary of common elements are:

- vulnerability risk assessments
- reviews of research impact
- considers both multiple marine industries
- development of adaptation options,
- stakeholder engagement
- management responses (e.g. EBFM)
- a need for funding and capacity

Thank you
