Plan of the presentation 話の内容

1. Introduction はじめに

The largest "island" of debris stretches 60 nautical miles (69 miles) in length and covers an expanse of more than 2.2 million square feet, according to the US Navy's 7th Fleet, which is closely monitoring the floating rubbish
Picture: REUTERS

2. Data Assimilation System: MOVE and K7 海洋のモデル、データ同化システム

3. Modelling of Drifting JTMD and Examples of the Model Solution 漂流物予測について

4. Summary まとめ

I. INTRODUCTION

Tragic event of the March 11, 2011 tsunami in Japan has generated estimated **1.5 million tons** of debris floating off the eastern Honshu (Japan Ministry of Environment, 2014).

This is an amount **comparable to the annual budget** of plastic marine debris of the entire North Pacific (Jambeck et al., 2015).

This Japan Tsunami Marine Debris (**JTMD**) was seen on photographs in the coastal areas.

Several weeks later, after JTMD drifted off shore and dispersed, its monitoring became very difficult.

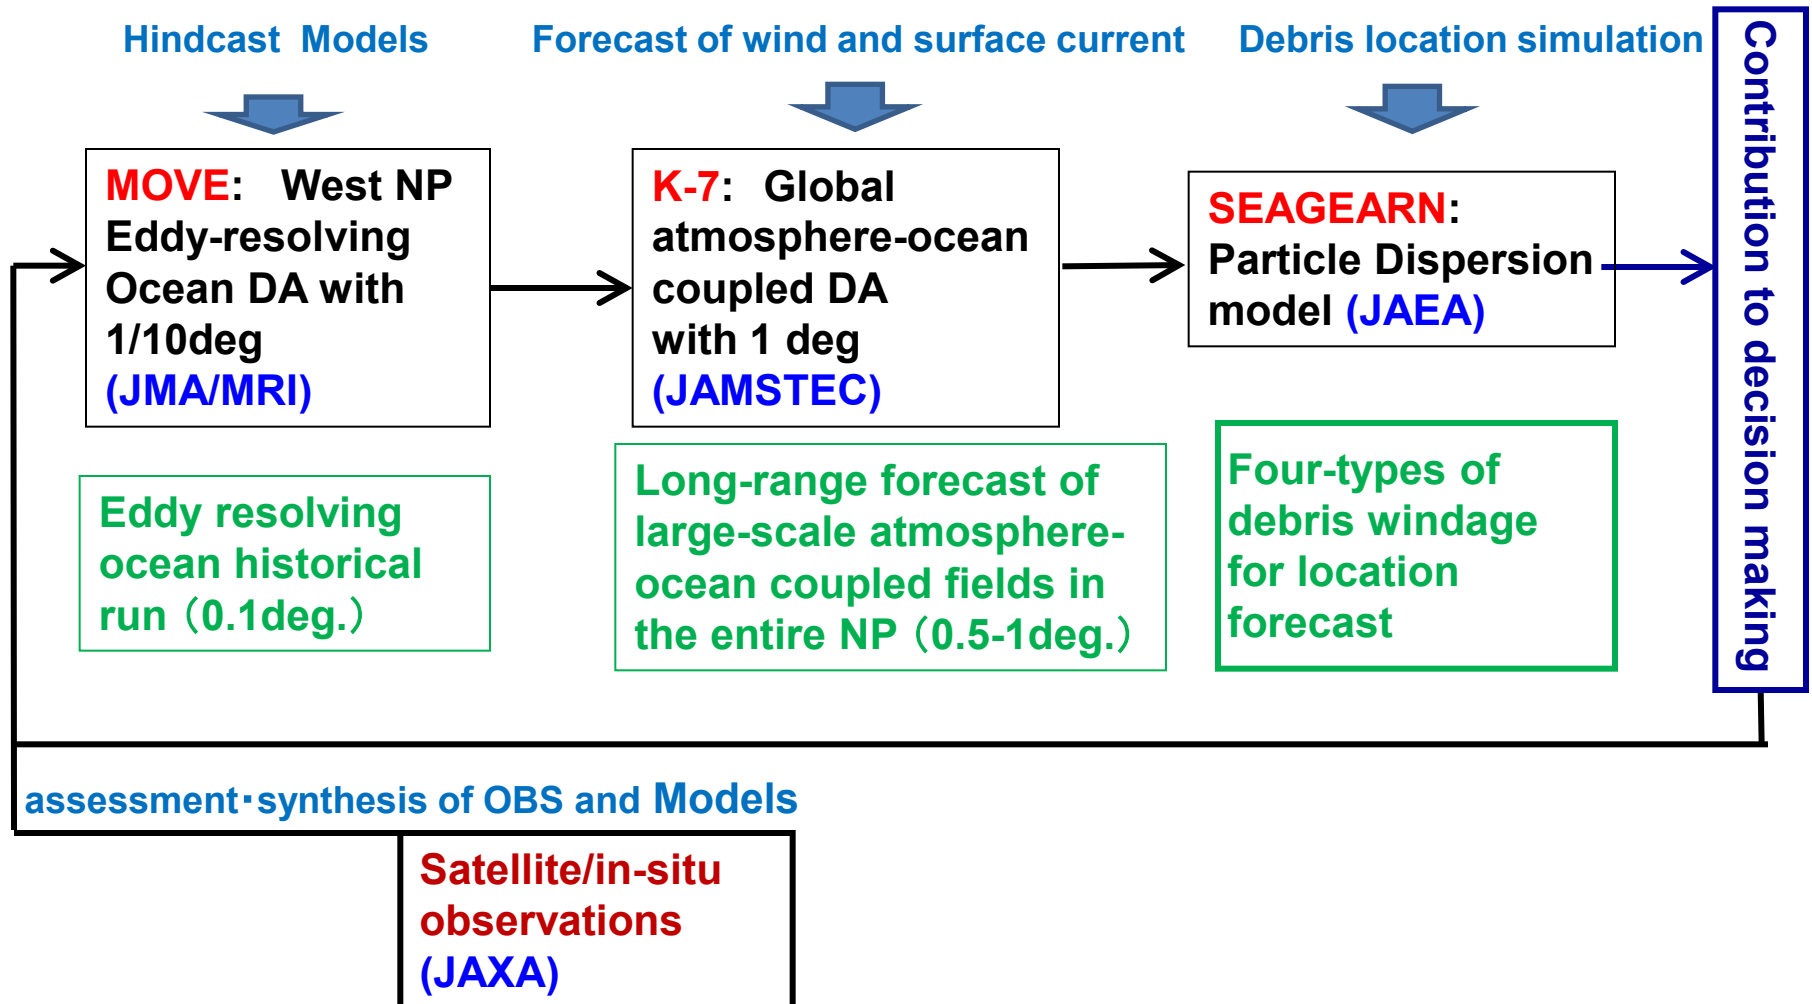

Sparse reports from the sea were not able to provide a **coherent description** of the pattern and drift motion of JTMD and this task was adopted **by numerical models**.

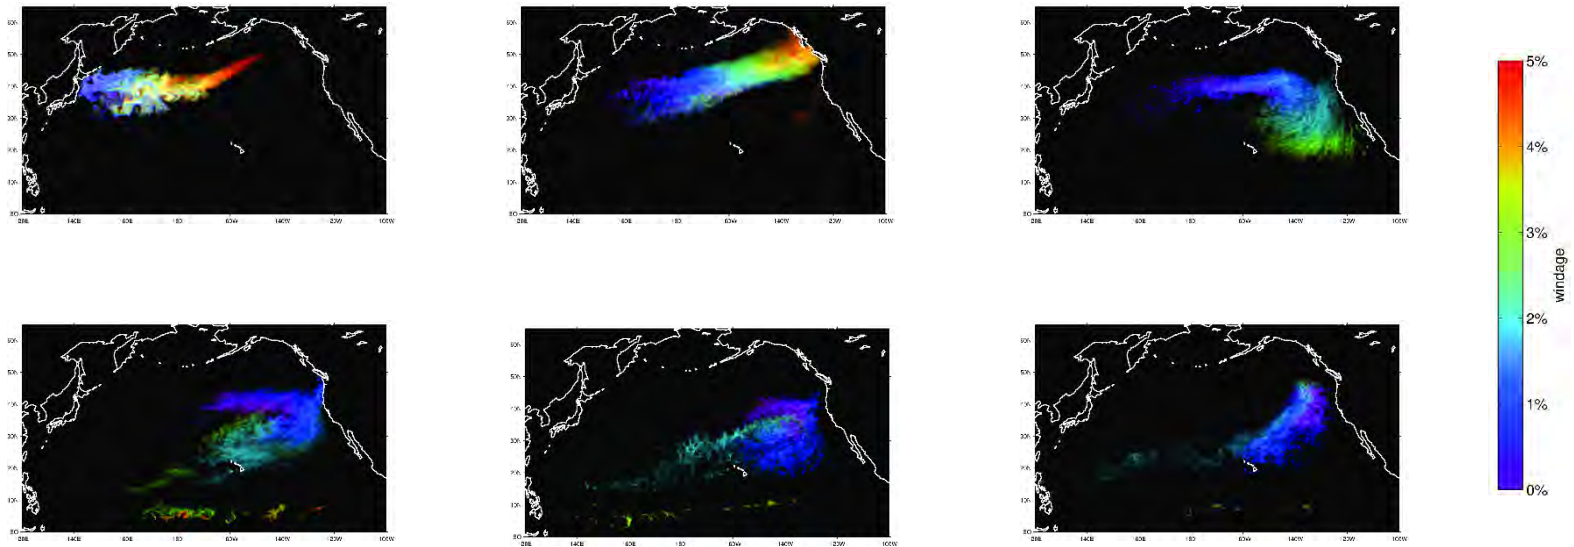

Figure 5. Evolution of JTMD tracer in the **SCUD** model simulations. Colors indicate windage of the debris. Shown are maps, corresponding to September 1, 2011, March 1, 2012, September 1, 2012, March 1, 2013, September 1, 2013, and March 1, 2014.

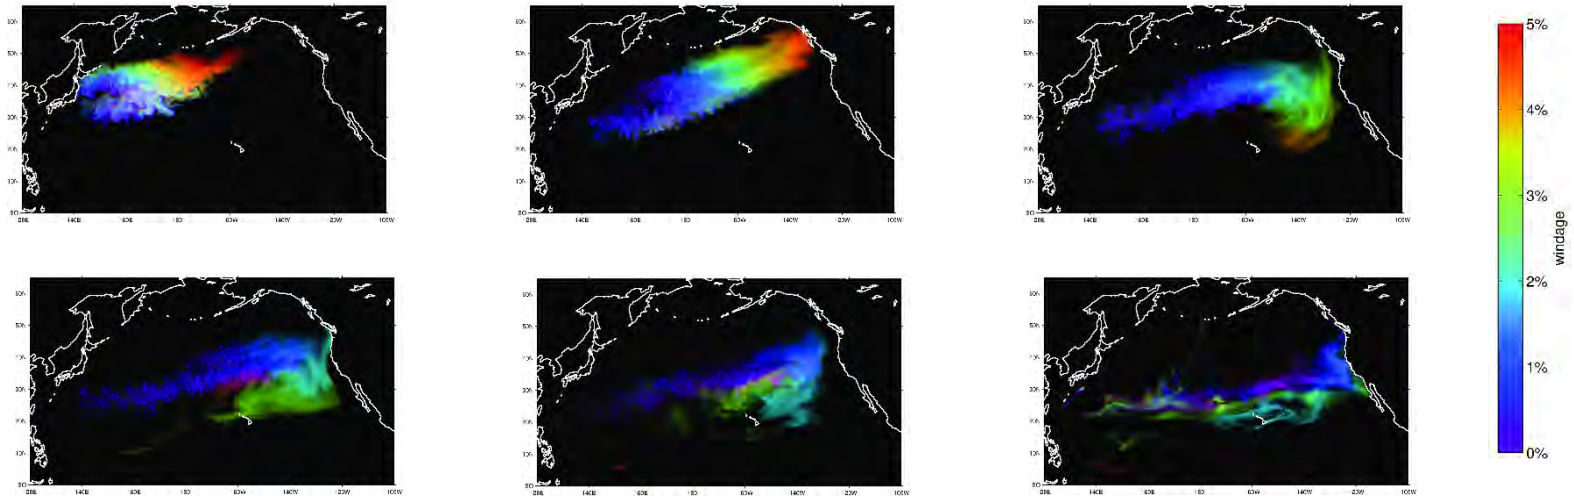

Figure 6. Same as in Figure 5 but for **MOVE/K-7/SEA-GEARN** model simulations.

米国海洋大気庁(NOAA)のシミュレーションシステム(GNOME)による結果

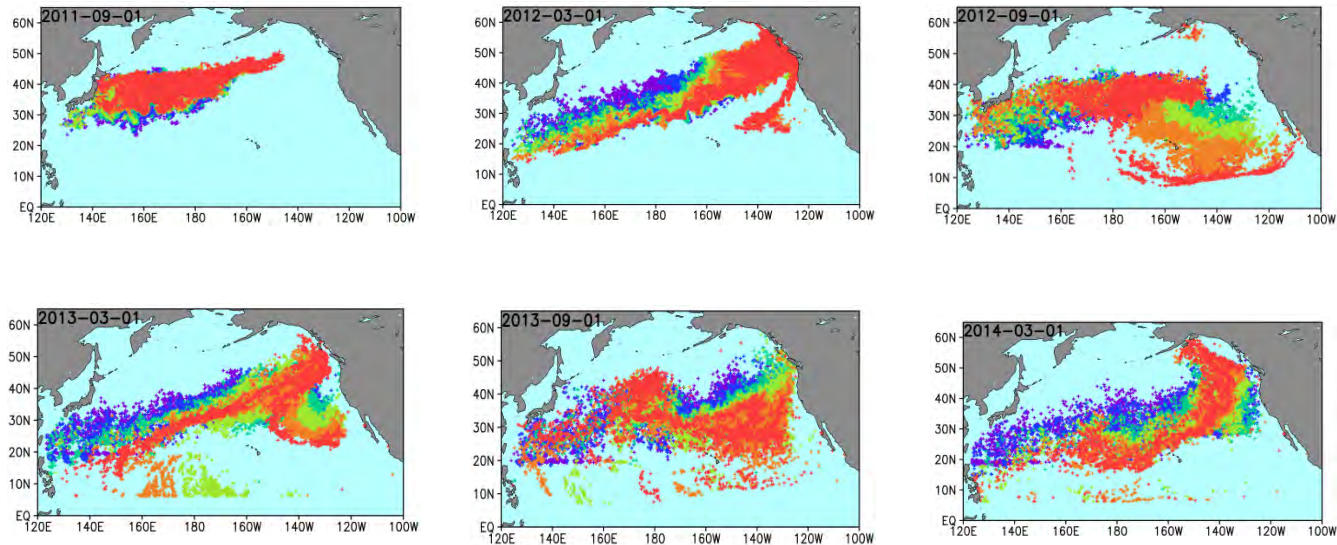

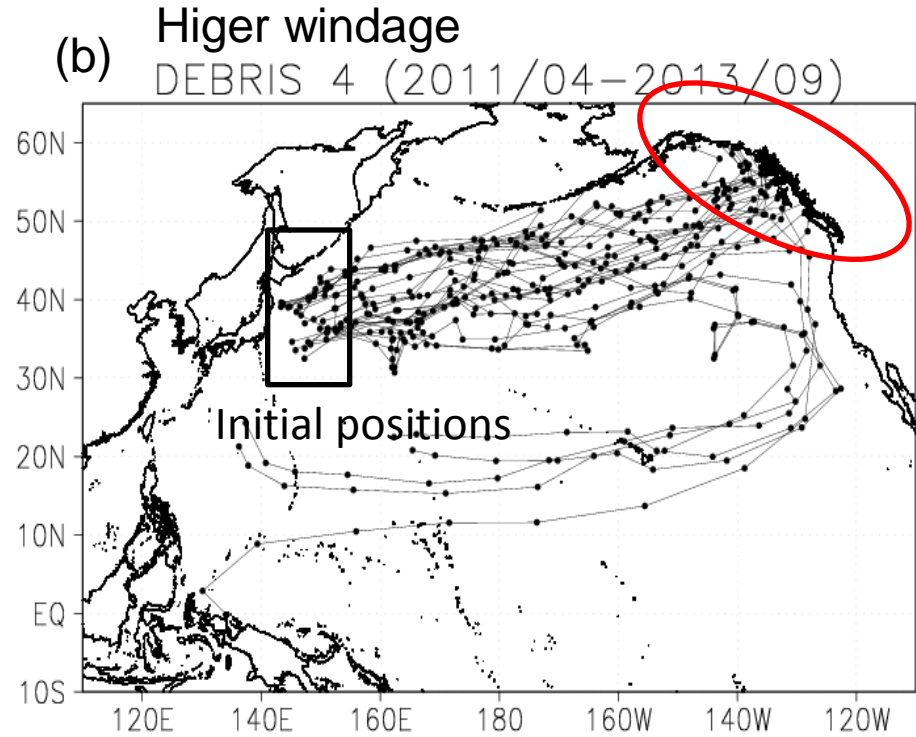

Figure 7. Same as in Figures 5 and 6 but for particle locations in the **GNOME** model simulations. Colors indicate particle windages according to the color scales of Figs. 5 and 6. High windages are plotted on a top of lower windages.

Typical debris trajectories with windages (a) 2.5% and (b) 5.0% from April 2011 to September, 2013.

Deterministic Trajectory

Probabilistic Trajectory

Dock WA 3% 2011-03-11 - 2012-12-18

Dock Molokai 4% 2011-03-11 - 2012-09-18

Probability density function of near-seasurface temperature, measured by the Argo network, along the probable path of Molokai dock

As shown in the figure (Maximenko et al., 2015b, and also Maximenko and Hafner, 2010), such approach gives not only the uncertainty of the trajectory of debris but also **probabilistic information of the sea environment (e.g., temperature) along the trajectory and time**. This information is critical for **detecting probable path of invasive species colonizing debris items**.

Example (Request)

Research Vessel (Kaisyou, 1.1ton) of Kesenuma Local Fisheries Laboratory (Miyagi prefectural Government) was found at about 6km offshore area from Miyako-city, Okinawa prefecture in May 12, 2016.

The prefectural government group would like to know the route.

Before 2011

(Lat=38.8, Lon=141.6)

After found in 2016/5/12

Example (Answer)
Probabilistic route

Kaisyou Boat windage=1.6% 2011-03-11 – 2016-05-12

Summary (some figures are not shown)

1. High computing simulation and data assimilation are useful for the calculation of marine debris distribution. The model solution depends on the windage.
2. On-shore observation and model solution estimated seasonal change: e.g., summer 2012, winter-spring 2013, spring-summer 2014, due to seasonal wind and ocean current fields.
3. Model solution estimates that less than 10% of the tracer washes ashore annually and suggests that more than 50% of JTMD with boat type windage was still floating in the end of 2016. This means that boats from the 2011 tsunami, built to withstand rough ocean conditions, will likely continue coming to the US/Canada coastline in several future years. At the same time, JTMD wandering in the gyre gradually mixes with marine debris from other sources and loses its identity.
4. Future progress in marine debris modeling requires radically improved at-sea and on-shore observing systems as well as better model descriptions of coastal process and processes on the sea surface (such as Stokes drift by wind waves) and their effects on floating objects.

Thank you for your attention

Content and Framework of JTF

Action of Japan to the drifting matters washed out by the March 11 Earthquake

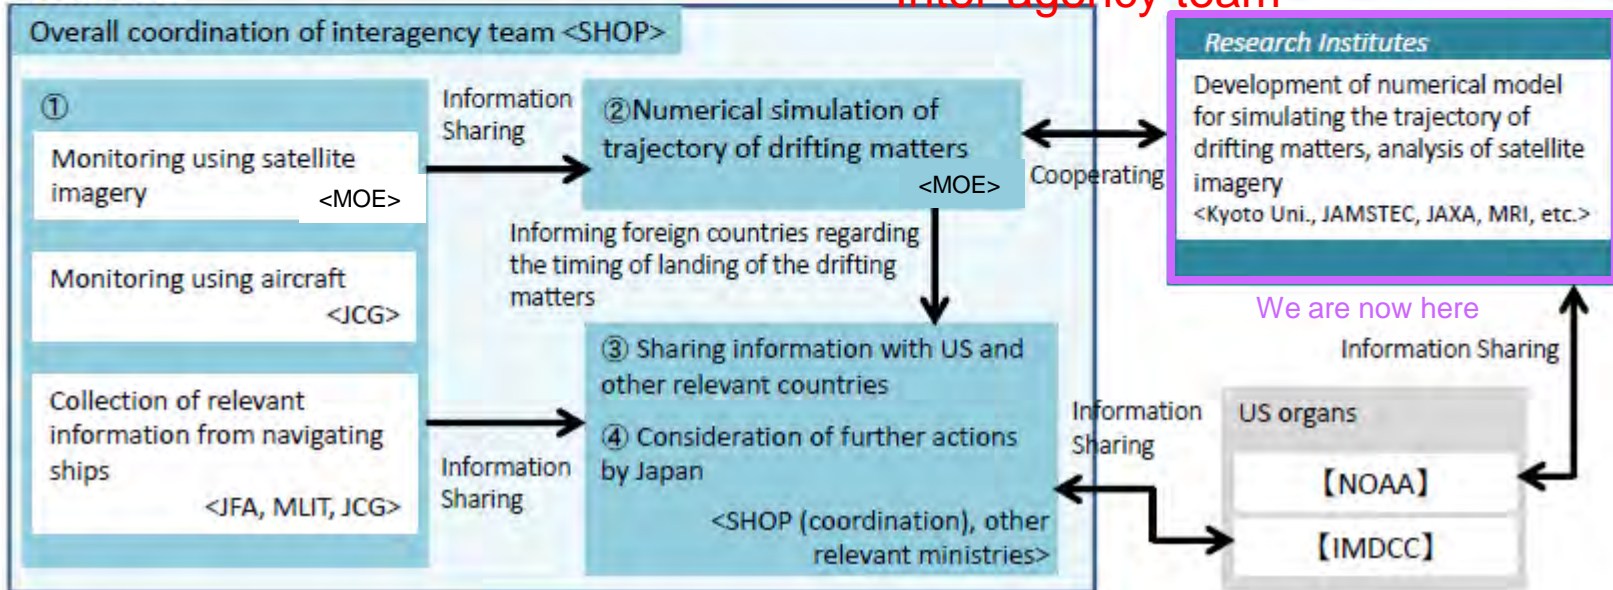

Current Situation

Tsunami triggered by the March 11 Earthquake washed out houses, containers etc. from the land, and made offshore matters such as fishery vessels, oyster beds and other fishing gears etc. loose. Some of them have sunk, others are still drifting. So far navigational problem regarding the drifting matters has not been reported partly owing to the navigational warning.

Future actions

Interagency team coordinated by the SHOP of CS will; 1. share the information with other countries which may be affected by the drifting matters 2. consider the further actions in the case of hazard to other countries including navigational problems, environmental risks, and the landfall of drifting matters to foreign countries by means of 1. monitoring the current status of drifting matters based on the reports from navigating ships, aerial observation and satellite imagery 2. prediction of trajectory by numerical simulation

Work Flow

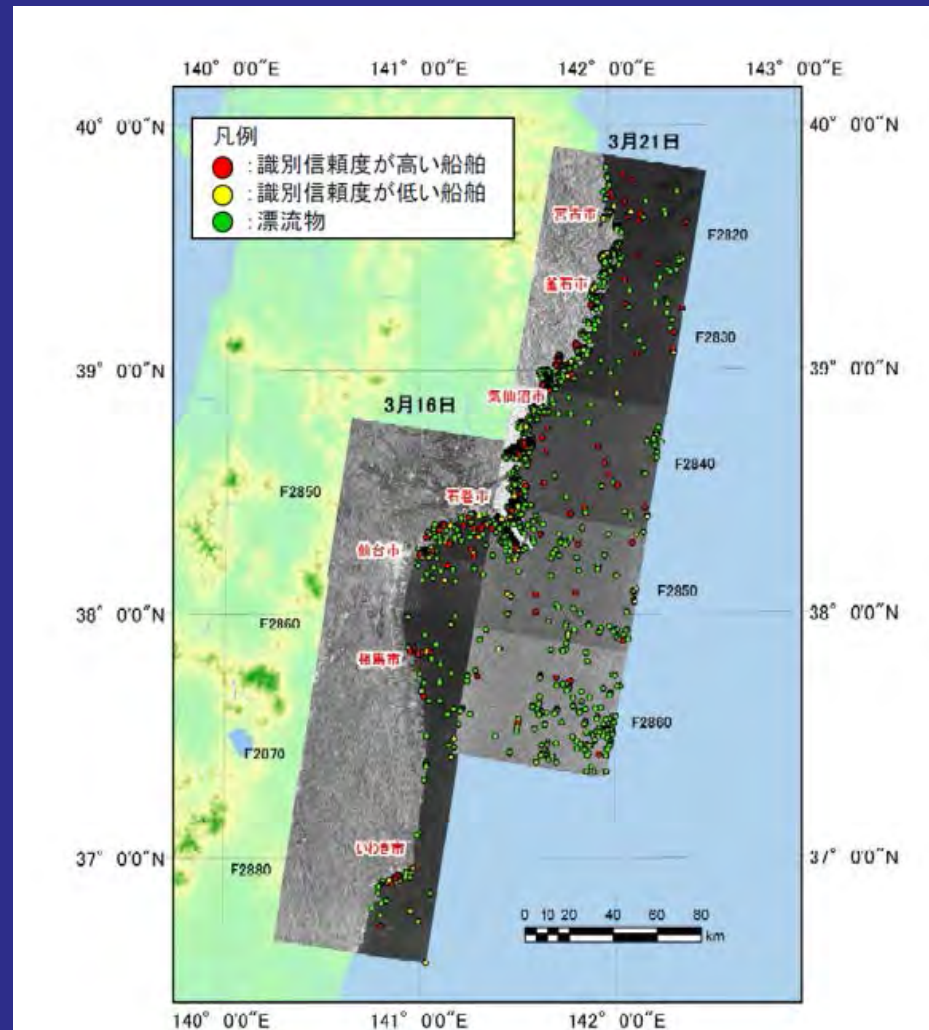

Japan Aerospace Exploration Agency (JAXA) acquired over 170 scenes for affected areas of the Great East Japan Earthquake by ALOS PALSAR.

Several ALOS data are analyzed to detect floating objects.

For example, approximately 2,000 objects, more than 6.3m in length, were detected from the observation data on Mar-16 and Mar-21.

Probabilistic Trajectory

The trajectories as well as distributions of debris have uncertainties, which can be expressed in a probabilistic way. For selected start and destination (or target) points, the uncertainties can be estimated from a combination of trajectories from the starting point forward in time and trajectories from the destination point backward in time in a manner of Fujii et al. (2013).

Chapman-Kolmogorov eqn.

$$p(B|F) = \int p(B|x, F)p(x|F)dx$$

Theoretical justification of the method was given in the forward (prediction) and backward (adjoint) models systems which are common in the data assimilation community. Holzer and Primeau (2008) and Fujii et al. (2013) used them to calculate the “**path density**” in different applications (e.g., **water mass movements**). In these studies the basic method is according to a balance that **the time derivative of forward variable multiplied by its adjoint variable equals with the divergence of terms derived from advection and diffusion**. Then the combined (multiplied) variable is conserved, and its distribution gives the probability density. Maximenko et al. (2015b) based their estimates on the interpretation of tracer concentration as a probability density of a single particle motions.

Probabilistic Trajectory: Theoretical Background

Method (Joint pdf) (Holzer & Primeau, 2008; Fujii et al., 2013)
(forward)x(backward full adjoint)

$$\rho(\mathbf{r}, \tau, \Omega_i, \Omega_f; t) = \frac{\rho(\mathbf{r}, t)}{M} \int_{t-\tau}^t dt_i \tilde{\mathcal{G}}(\mathbf{r}, t | \Omega_f, t_i + \tau) \mathcal{G}(\mathbf{r}, t | \Omega_i, t_i)$$

The equation is annotated with two teal curved arrows pointing downwards from the terms $\tilde{\mathcal{G}}(\mathbf{r}, t | \Omega_f, t_i + \tau)$ and $\mathcal{G}(\mathbf{r}, t | \Omega_i, t_i)$ to the text "(backward full adjoint)" in the block above.

$$\mathbf{J}(\mathbf{r}, t | \Omega_i, t_i) \equiv [\rho \mathbf{u} - \rho \mathbf{K} \nabla] \mathcal{G}(\mathbf{r}, t | \Omega_i, t_i)$$
