Sensitivity of marine systems to climate and fishing: Concepts, issues and management responses
 R. Liu Perry, P. Phillips, C. Stepien, M. Stoeckl, S. Simon Jennings

ARTICLE INFO
 Volume 115, January 2013
 Pages 1-10
 ISSN 0969-1254
 DOI: 10.1016/j.jmsys.2012.12.001

ABSTRACT
 Marine fisheries and coastal ecosystems are highly sensitive to climate change and fishing pressure. This review examines the interactions between climate change and fishing pressure on marine systems and discusses the implications for management. The review highlights the need for integrated management approaches that take account of both climate change and fishing pressure. Key areas for research and management are identified, including the need to improve our understanding of the interactions between climate change and fishing pressure, and to develop more effective management strategies that take account of both climate change and fishing pressure.

1. Introduction
 Variability is an inherent characteristic of marine ecosystems (Pauly and Christy, 2001). This variability is due to a combination of natural and anthropogenic factors. Natural variability is caused by a range of factors, including changes in ocean circulation, climate, and biological processes. Anthropogenic variability is caused by human activities, such as fishing and climate change. This review examines the interactions between climate change and fishing pressure on marine systems and discusses the implications for management.

Abstract:
 This report provides an overview of the current state of the Pacific Ocean in British Columbia, Canada. It discusses the challenges facing the Pacific Ocean and the need for integrated management approaches that take account of both climate change and fishing pressure.

Summary (so far) - Products

- Long-term warming and freshening, but with year-to-year variability
- Seasonal cycles of major zooplankton species are shifting earlier
- Abundances of key forage fish species such as herring are low in many areas of BC coast, even with no fishing
- Salmon which feed lower in the food web have generally been doing well; those feeding higher in the food web have been doing less well

STATE OF THE PACIFIC OCEAN 2012

Figure 1. The Pacific waters of British Columbia, Canada.

Context:

Pacific Canadian waters lie in a transition zone between coastal upwelling (California Current) and downwelling (Alaskan Coastal Current) regions, and experience strong seasonality and considerable freshwater influence. Variability is closely coupled with events and conditions throughout the tropical and North Pacific Ocean, experiencing frequent El Niño and La Niña events particularly over the past decade. The region supports important resident and migratory populations of invertebrates, groundfish and pelagic fishes, marine mammals and seabirds.

Monitoring the physical and biological oceanographic conditions and fishery resources of this region is done semi-regularly by several government departments, to understand the natural variability of these ecosystems and how they respond to both natural and anthropogenic stresses. Support for these programs is provided by Fisheries and Oceans Canada (DFO), and Environment Canada. Contributors to this report are members of the Fisheries Oceanography Working Group of the DFO Centre for Science Advice Pacific Region (CSAP), with additional contributions from other Canadian and American fisheries and climate scientists.

This Science Advisory Report is from the February 20-21, 2013 State of the Ocean: 2013 Workshop. Additional publications from this workshop will be posted on the [Fisheries and Oceans Canada \(DFO\) Science Advisory Schedule](#) as they become available.

Projecting climate impacts on food webs

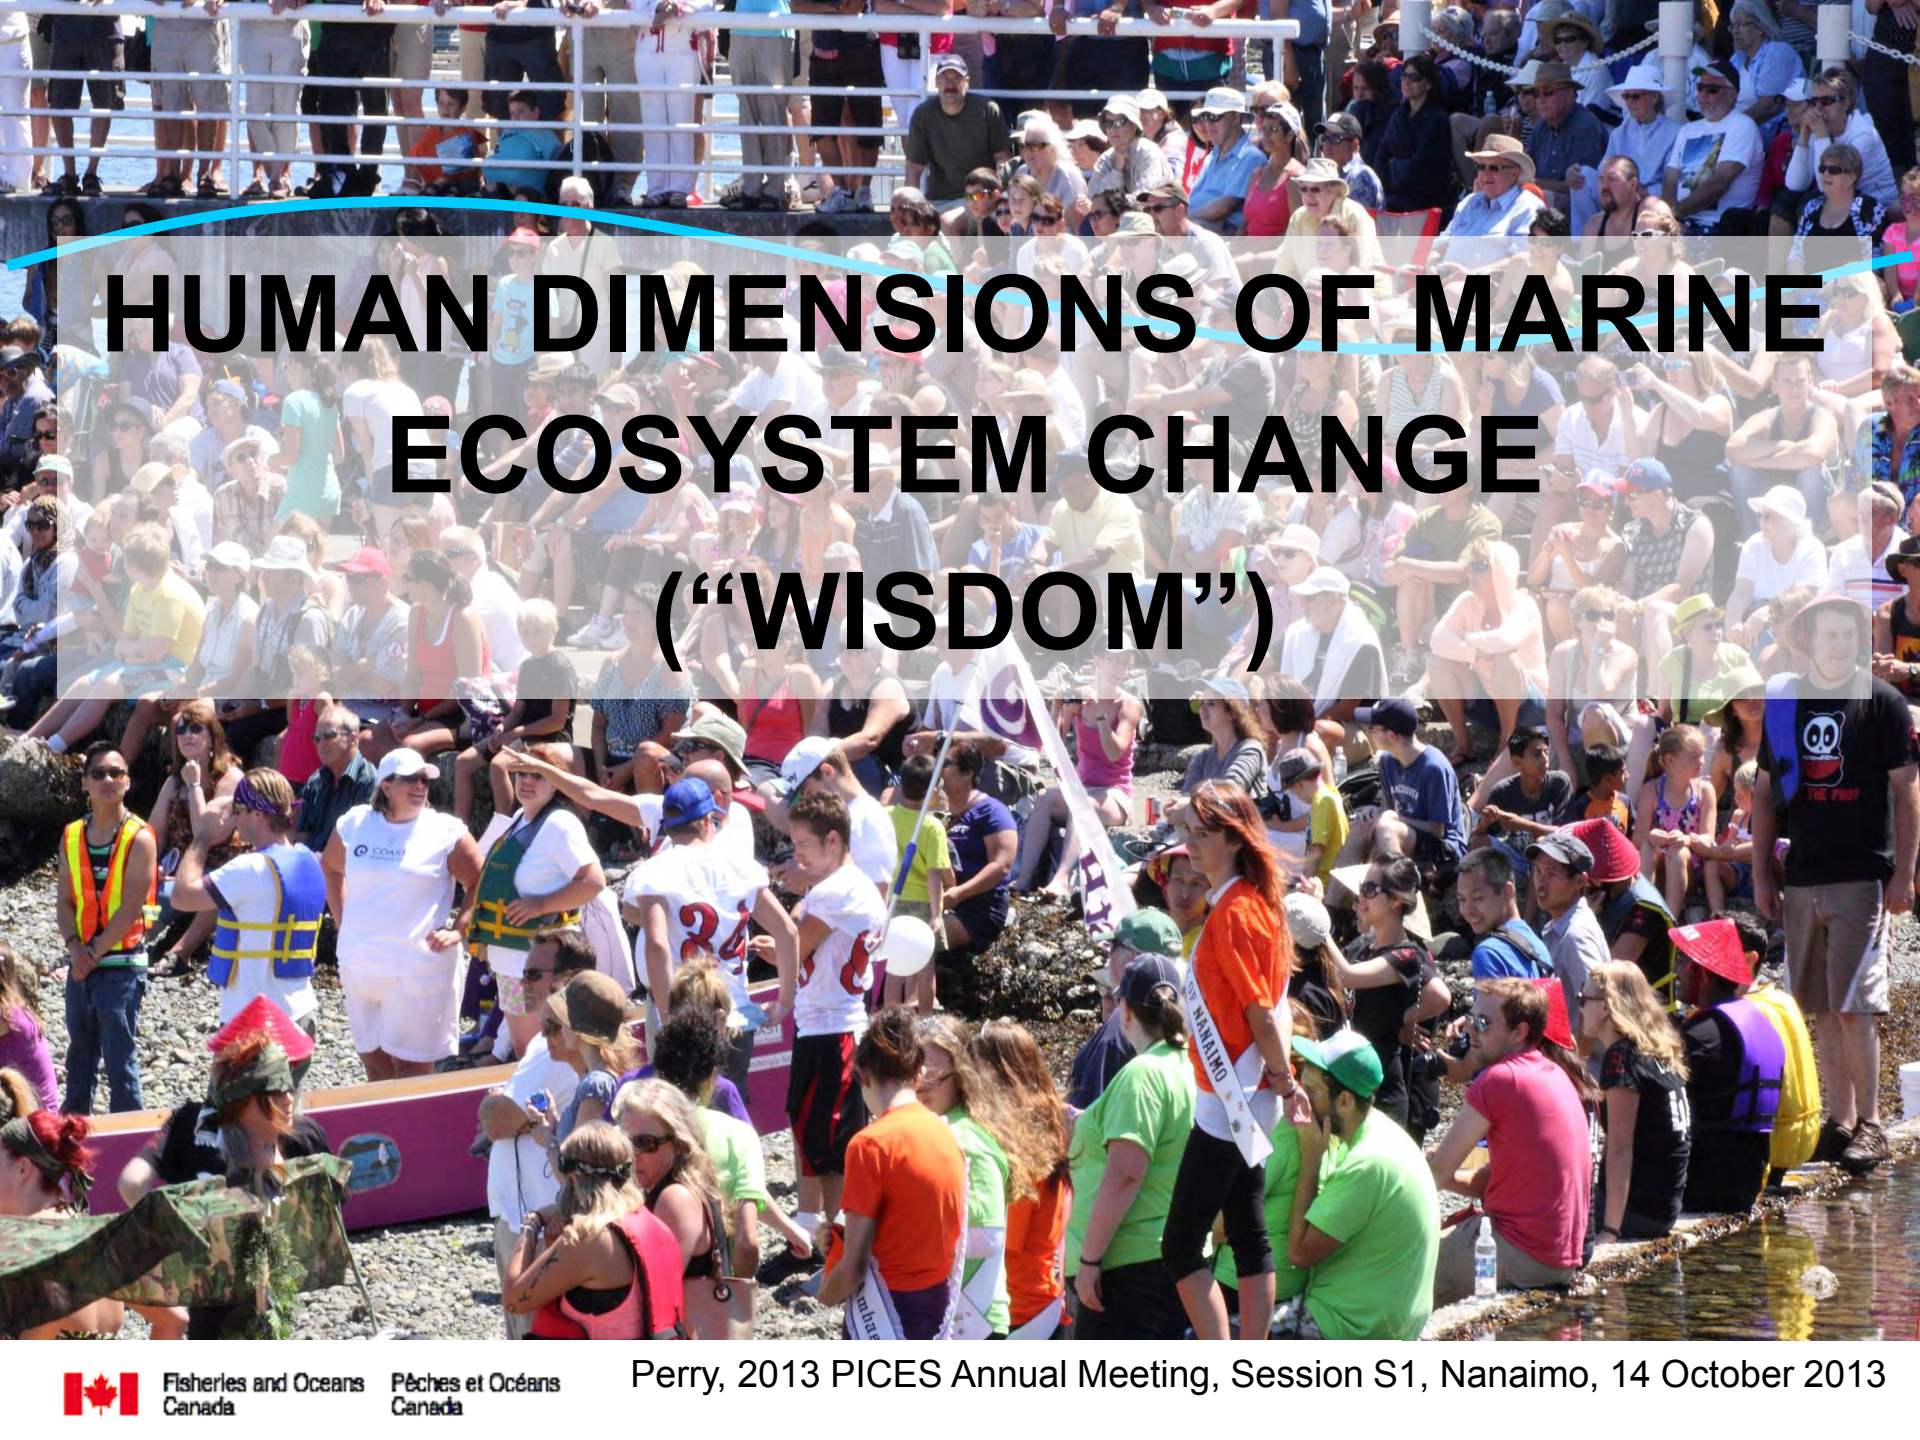

Projecting climate impacts on food webs

Summary (so far) – uncertainty and future projections

- Warming trend is predicted overall, but on time scales <20 years cooling trends are almost as likely
- 40 years from now, predict warmer and fresher everywhere, especially in winter
- Outcomes for species at top of food web are uncertain: could be better, or worse, than now
 - worst situation would be several consecutive years with low abundances – ratchet effect

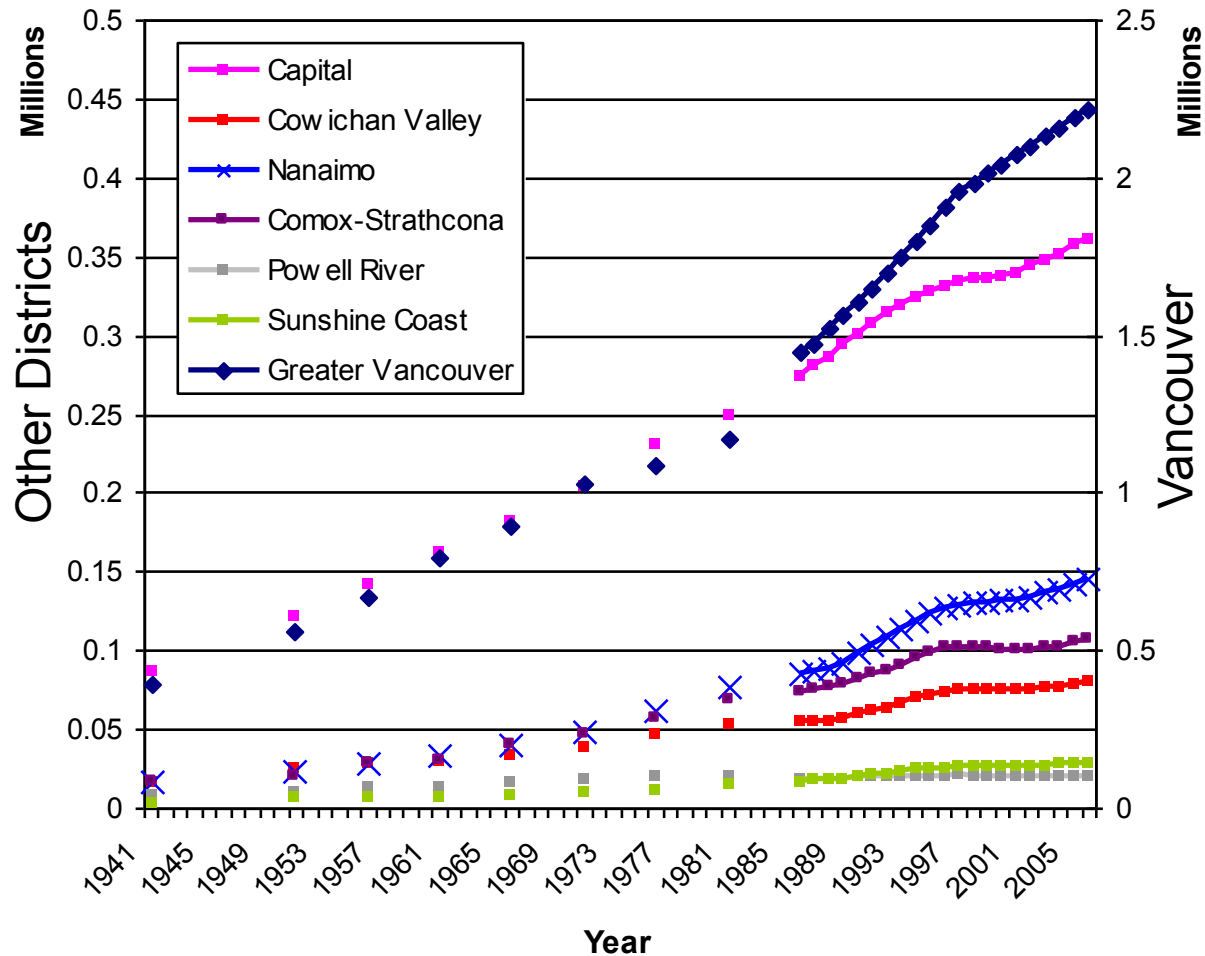

HUMAN DIMENSIONS OF MARINE ECOSYSTEM CHANGE ("WISDOM")

People as drivers of change: Human population around the Strait of Georgia

Population increases from 1986 to 2006:

Livelihood security in BC fishing industry

Employment in fish processing has been supported by imports of raw products for processing, diversification into different species, and processing of aquaculture products

Responses of fishing-dependent human communities to changes in marine ecosystems

- at short time scales (**coping strategies**):
 - intensification of fishing
 - diversification to other species and gears
 - migration to follow the fish
 - hibernation (family and social assistance)
- at longer time scales (**adapting strategies**):
 - education and skills upgrading
 - diversification to other industries
 - political action
 - abandonment of the community

AN INFORMATION BULLETIN ON GLOBAL ENVIRONMENTAL CHANGE AND HUMAN SECURITY
ISSUE NO. 6

The Index of Human Insecurity

Introduction

Traditional perspectives on security have been conceived of primarily in terms of neutralizing military threats to the territorial integrity and political independence of the state. However, in recent years, there has been increased emphasis placed on expanding the traditional conception of security to include so-called non-conventional threats. These include: resource scarcity, rapid population growth, human rights abuses, outbreaks of infectious disease, environmental degradation caused by toxic contamination, ozone depletion, global warming, water pollution, soil degradation and the loss of biodiversity (cf. Ullman, 1983; Renner, 1989; Westing, 1989). It is now accepted that *environmental stress, often the result of global environmental change, coupled with increasingly vulnerable societies, may contribute to insecurity and even conflict.*

As our perspective on security changes, it is important to adapt our policy framework to meet this change. One alternative is to focus on *human security*, recognizing the inter-linkages of environment and society, and acknowledging that our perceptions of our environment and the way we interact

ISSUE NO. 1

Environmental Change, Vulnerability and Security in the Pacific

INTRODUCTION

Intuitively at least, we have a sense that environmental change has the potential to undermine human security. The degradation of resources can negatively affect the capacity of people to sustain their livelihoods. Accessibility to basic necessities such as food can be reduced by environmental change and there are widespread effects upon human health that can be linked directly to changes in the quality of the environment. Peoples' sense of security can be influenced also when resource exploitation and environmental change have impacts upon local communities, cultural norms and traditions, and socio-political structures. In some acute cases, the insecurities that arise from environmental change may lead to violent conflict.

It is much more difficult to establish precisely what the connections are between environmental change and human security. Land degradation, for example, threatens the economic and food security of people around the world, but the underlying causes often can be traced to complex processes of economic and political transformation that extend across regional, national and international territories.

In such a process, insecurity is not a simple matter of control and control. It is a complex of many factors, each of which has its own dynamics and its own impact on the whole. It is a complex of many factors, each of which has its own dynamics and its own impact on the whole.

Food Security in a Changing World

What is Food Security?

"Food Security" is easily discussed in general terms, but it embodies a complex set of intertwined concerns and issues. The concept continues to evolve, with almost 200 definitions proposed since 1975. A universally accepted definition remains elusive, but most contemporary conceptions present food security as *people having access to sufficient stocks and supplies of food to provide a nutritionally adequate diet.*

Accurate and timely measures of food insecurity are difficult to obtain. Malnutrition and hunger are often employed as surrogate measures, but actually represent the most advanced and chronic forms of food insecurity. Food insecurity occurs long before malnutrition and hunger set in, therefore using these indicators greatly underestimates the number of individuals suffering food insecurity.

One indicator regularly used to establish a standard or threshold for separating undernourished persons from others is minimum recommended dietary allowances (RDAs). Nutritionists continue to debate what the minimum value ought to

be and whether the complex relationship between diet and human development is represented adequately by a single indicator such as caloric intake. Methods for estimating RDAs, as well as designation of minimum thresholds, vary amongst agencies and countries, and sometimes result in diverging estimates of food insecurity.

Malnutrition estimates derived from macro-scale national studies provide little insight into the distribution of hunger within a region or country. For example, national average per capita caloric intake in Sri Lanka and India are similar – both are above 2000 cal/day – but a smaller portion of Sri Lankans suffer from hunger. Elsewhere, a recent FAO report estimates that even in countries with a food supply in the 2700 cal/day range, which is well above recognized minimum RDAs, at least 10% of the population is undernourished.

Data availability and quality also impede the establishment of reliable and precise measures of food insecurity. Inadequate public infrastructure makes obtaining

"Despite massive increases in world food production, food insecurity persists."

**WHERE IS THE WISDOM WE HAVE LOST
IN KNOWLEDGE?**

**WHERE IS THE KNOWLEDGE WE HAVE
LOST IN INFORMATION?**

T.S. Eliot
The Rock (1934)

Conclusions:

Canada as a Case Study for FUTURE

“Information”

- Canadian marine ecosystems are changing in important ways
 - we are observing and reporting these changes

“Knowledge”

- Tools to identify and integrate multiple stressors and their effects on Canadian marine ecosystems
- Projections of future conditions including uncertainty

“Wisdom”

- “Human Dimensions” as drivers of change and support of food and livelihood security
- Tools to test management actions in uncertain futures
- Communication is key

What can we do – individually, and as members of PICES?

Marine environmental change matters to people

As individuals:

- Integrate People as drivers, and recipients, of ecosystem change, and effects on human well-being, into our research
- Seek opportunities to communicate our results to a wide range of audiences using plain language

As PICES:

- Provide accessible summaries of ocean conditions
- Develop community tools for understanding stressors and impacts
- Prepare Science Advisory Reports on important topics
