Development of multispecies models to investigate predator-prey interactions and temperature-mediated predation rates of Pacific cod and other groundfish in the eastern Bering Sea

Tadayasu Uchiyama, Gordon H. Kruse, and Franz J. Mueter

University of Alaska Fairbanks, School of Fisheries and Ocean Sciences, Juneau, Alaska, USA

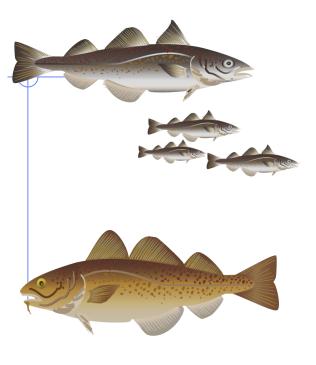

Motivation

- Groundfish from the eastern Bering Sea (EBS) account for ~40% of all US commercial landings
- EBS groundfish landings are mainly walleye pollock, Pacific cod, and various flatfish species
- Strong and weak year classes of pollock and cod tend to coincide, but flatfish tend to have opposite trends
- Are these patterns due to predator-prey relationships or responses to the environment?
- Can knowledge of the interactions lead to a joint management approach?

Objectives

- Develop multispecies biomass dynamics (MBD) and multispecies delay difference (MDD) models of EBS groundfish species with predatory interactions
- 2. Project fish biomasses under different management scenarios
- 3. Investigate the effects of climate on predation and dynamics of the species

Conceptual Model

Species

Walleye pollock

Adult pollock (Age 3+)

Juvenile pollock (Age 0, 1, & 2)

Pacific cod

Pacific cod (Age 1+)

Arrowtooth flounder

Arrowtooth flounder (Age 1+)

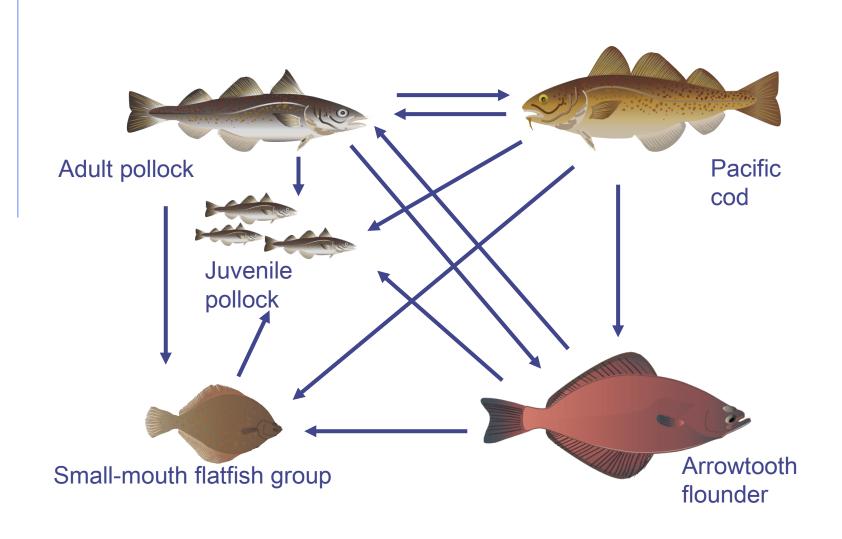

Northern rock sole, Alaska plaice

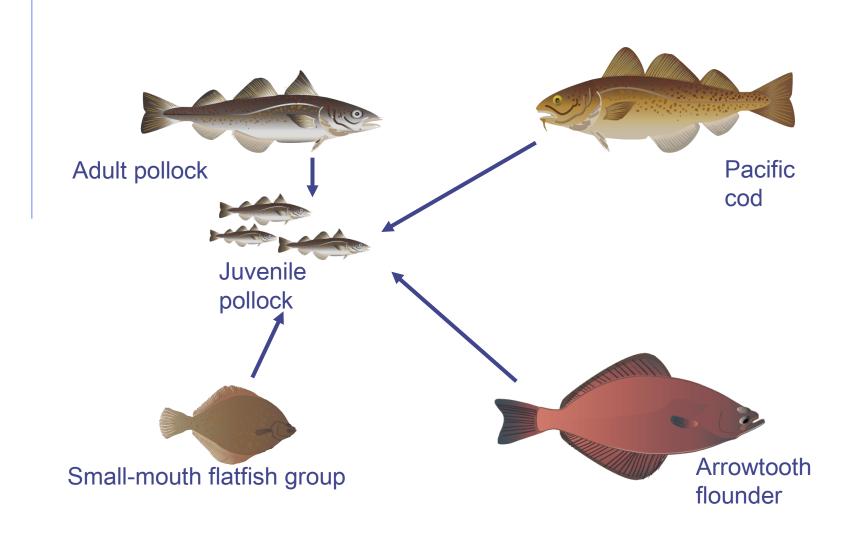

Flathead sole, Yellowfin sole

Small-mouth flatfish (Age 1+)

Modeled Trophic Relationships

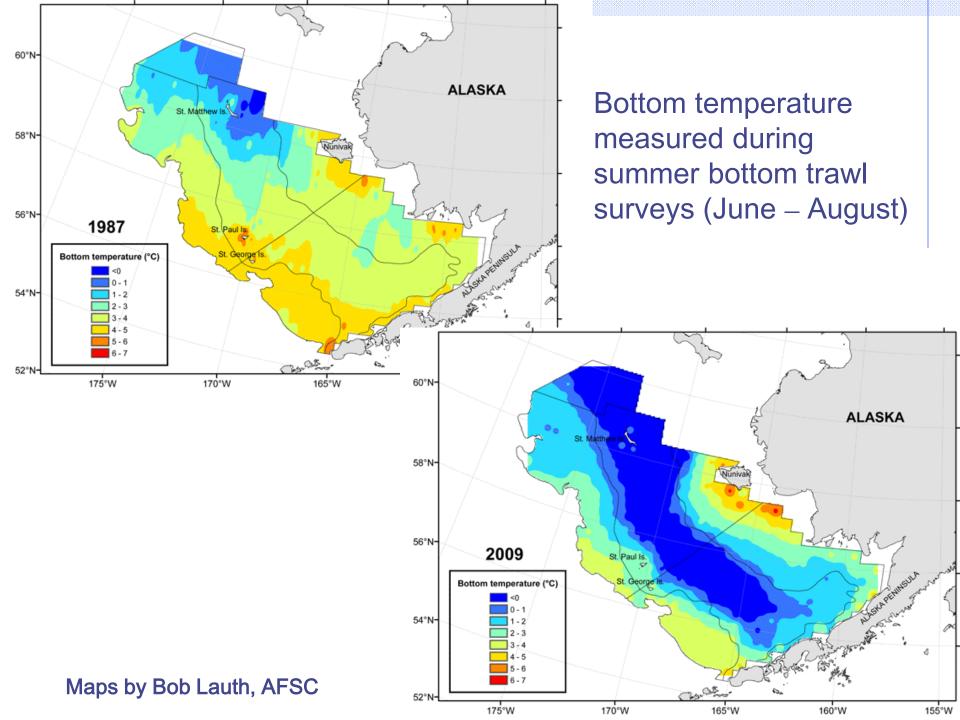

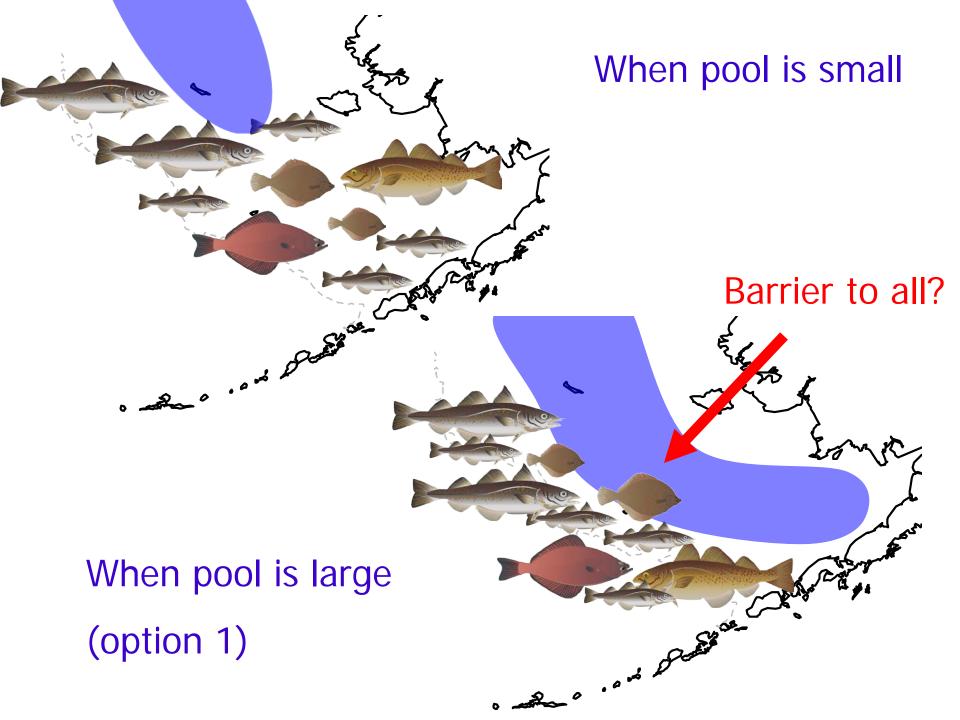

Juvenile Pollock as Prey

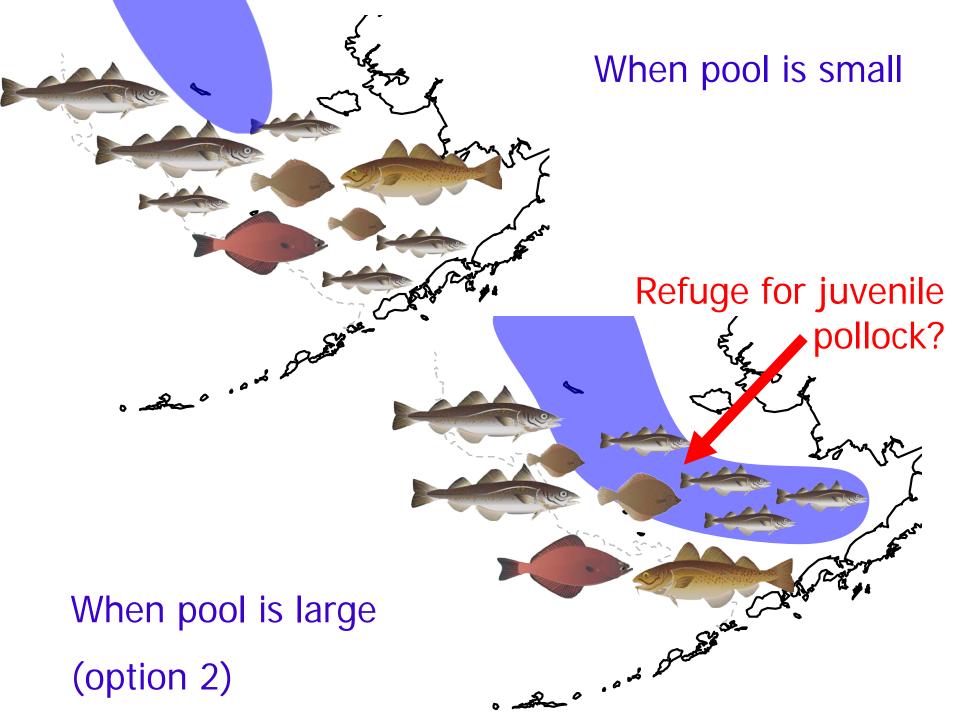

The Cold Pool & Fish Ecology

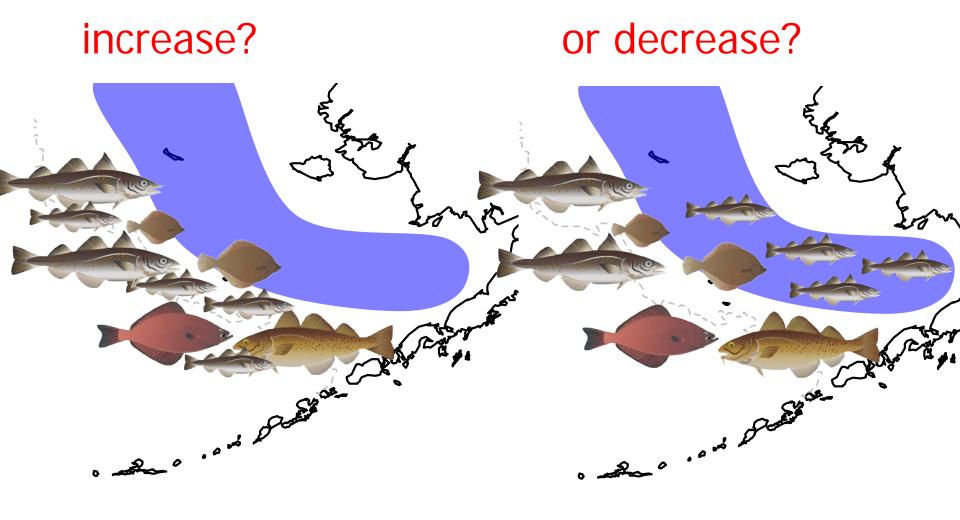

- Cold pool is a body of very cold water (< 2°C) on the EBS shelf
- Forms in winter when sea ice freezes
- Size of cold pool in summer depends on extent of sea ice the previous winter
- Many subarctic fish avoid cold pool
- Some evidence that age-1 pollock can tolerate colder temperatures than adults

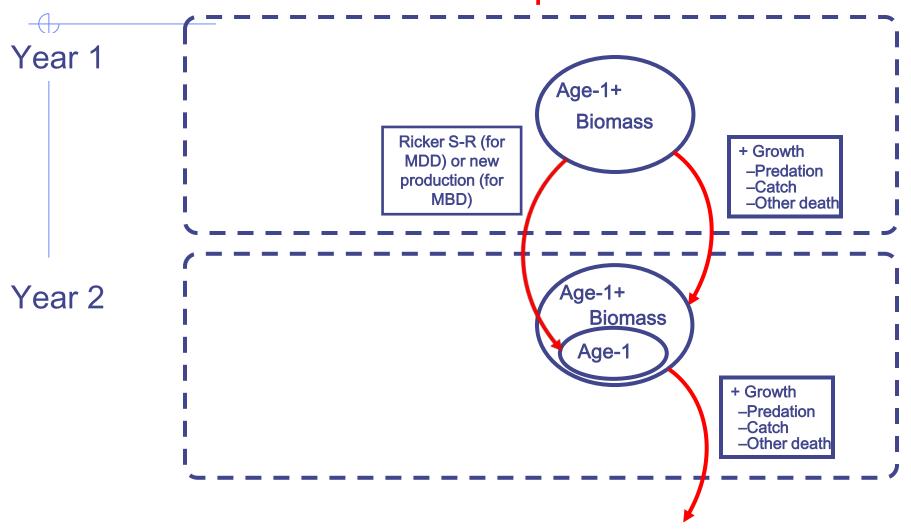

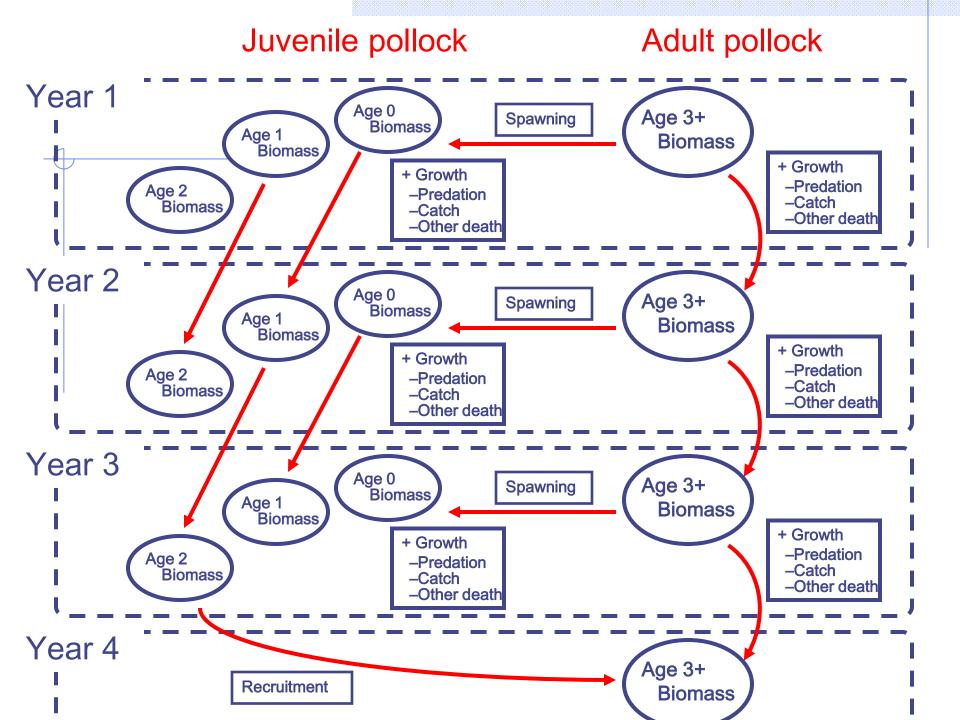

With extensive cold pool, does predation

Pacific Cod, Arrowtooth Flounder, and Small-mouth Flatfish Group

Modeling of Juvenile Pollock

- Juvenile pollock (ages 0, 1, and 2) were modeled with age structure to account for predation on recruitment at each juvenile stage
- Age-0 pollock modeled to be proportional to adult (age 3+) biomass
- Age-1, age-2, and age-3 pollock biomasses estimated sequentially by accounting for growth, predation, and commercial catch (age-2 and age-3 only)
- Juveniles were modeled identically in MBD and MDD models

Multispecies Biomass Dynamics Model

Basic equation form for species x in year y+1:

$$\hat{B}_{x,y+1} = \hat{B}_{x,y} + r_x \hat{B}_{x,y} \Biggl(1 - \frac{\hat{B}_{x,y}}{k_x} \Biggr) - C_{x,y} - \hat{B}_{pred,x,y} \,, \label{eq:Bxy}$$

where $\hat{B}_{x,y}$ = biomass estimate of species x in year y,

 $C_{x,y}$ = commercial catch in year y,

 $\hat{B}_{pred,x,y}$ = estimated predation on species x in year y, and

 r_x , k_x = population growth and carrying capacity parameters, respectively, for species x.

Multispecies Biomass Dynamics Model

Equation for pollock also includes a recruitment term:

$$\hat{B}_{p,y+1} = \hat{B}_{p,y} + r_p \hat{B}_{p,y} \left(1 - \frac{\hat{B}_{p,y}}{k_p} \right) - C_{p,y} - \hat{B}_{pred,p,y} \left(+ \hat{R}_{p,y+1}, \frac{\hat{B}_{p,y}}{k_p} \right) - C_{p,y} - \hat{B}_{pred,p,y} \left(+ \hat{R}_{p,y+1}, \frac{\hat{B}_{p,y}}{k_p} \right) - C_{p,y} - \hat{B}_{pred,p,y} \left(+ \hat{R}_{p,y+1}, \frac{\hat{B}_{p,y}}{k_p} \right) - C_{p,y} - \hat{B}_{pred,p,y} \left(+ \hat{R}_{p,y+1}, \frac{\hat{B}_{p,y}}{k_p} \right) - C_{p,y} - \hat{B}_{pred,p,y} \left(+ \hat{R}_{p,y+1}, \frac{\hat{B}_{p,y}}{k_p} \right) - C_{p,y} - \hat{B}_{pred,p,y} \left(+ \hat{R}_{p,y+1}, \frac{\hat{B}_{p,y}}{k_p} \right) - C_{p,y} - \hat{B}_{pred,p,y} \left(+ \hat{R}_{p,y+1}, \frac{\hat{B}_{p,y}}{k_p} \right) - C_{p,y} - \hat{B}_{pred,p,y} \left(+ \hat{R}_{p,y+1}, \frac{\hat{B}_{p,y}}{k_p} \right) - C_{p,y} - \hat{B}_{pred,p,y} \left(+ \hat{R}_{p,y+1}, \frac{\hat{B}_{p,y}}{k_p} \right) - C_{p,y} - \hat{B}_{pred,p,y} \left(+ \hat{R}_{p,y+1}, \frac{\hat{B}_{p,y}}{k_p} \right) - C_{p,y} - \hat{B}_{pred,p,y} \left(+ \hat{R}_{p,y+1}, \frac{\hat{B}_{p,y}}{k_p} \right) - C_{p,y} - \hat{B}_{pred,p,y} \left(+ \hat{R}_{p,y+1}, \frac{\hat{B}_{p,y}}{k_p} \right) - C_{p,y} - \hat{B}_{pred,p,y} \left(+ \hat{R}_{p,y+1}, \frac{\hat{B}_{p,y}}{k_p} \right) - C_{p,y} - \hat{B}_{pred,p,y} \left(+ \hat{R}_{p,y+1}, \frac{\hat{B}_{p,y}}{k_p} \right) - C_{p,y} - \hat{B}_{pred,p,y} \left(+ \hat{R}_{p,y+1}, \frac{\hat{B}_{p,y}}{k_p} \right) - C_{p,y} - \hat{B}_{pred,p,y} \left(+ \hat{R}_{p,y+1}, \frac{\hat{B}_{p,y}}{k_p} \right) - C_{p,y} - \hat{B}_{p,y} \left(+ \hat{R}_{p,y+1}, \frac{\hat{B}_{p,y}}{k_p} \right) - C_{p,y} - \hat{B}_{p,y} \left(+ \hat{B}_{p,y}, \frac{\hat{B}_{p,y}}{k_p} \right) - C_{p,y} - \hat{B}_{p,y} \left(+ \hat{B}_{p,y}, \frac{\hat{B}_{p,y}}{k_p} \right) - C_{p,y} - \hat{B}_{p,y} \left(+ \hat{B}_{p,y}, \frac{\hat{B}_{p,y}}{k_p} \right) - C_{p,y} - \hat{B}_{p,y} \left(+ \hat{B}_{p,y} \right) - C_{p,y} - \hat{B}_{p,y} \left(+ \hat{B}_{p,y}, \frac{\hat{B}_{p,y}}{k_p} \right) - C_{p,y} - \hat{B}_{p,y} \left(+ \hat{B}_{p,y}, \frac{\hat{B}_{p,y}}{k_p} \right) - C_{p,y} - \hat{B}_{p,y} \left(+ \hat{B}_{p,y}, \frac{\hat{B}_{p,y}}{k_p} \right) - C_{p,y} - \hat{B}_{p,y} \left(+ \hat{B}_{p,y}, \frac{\hat{B}_{p,y}}{k_p} \right) - C_{p,y} - \hat{B}_{p,y} \left(+ \hat{B}_{p,y}, \frac{\hat{B}_{p,y}}{k_p} \right) - C_{p,y} - \hat{B}_{p,y} \left(+ \hat{B}_{p,y}, \frac{\hat{B}_{p,y}}{k_p} \right) - C_{p,y} - \hat{B}_{p,y} \left(+ \hat{B}_{p,y} \right) - C_{p,y} - \hat{B}_{p,y} \left(+ \hat{B}_{p,y}, \frac{\hat{B}_{p,y}}{k_p} \right) - C_{p,y} - \hat{B}_{p,y} \left(+ \hat{B}_{p,y}, \frac{\hat{B}_{p,y}}{k_p} \right) - C_{p,y} - \hat{B}_{p,y} \left(+ \hat{B}_{p,y}$$

where $\hat{R}_{p,v+1}$ = predicted recruitment.

Multispecies Delay Difference Model

Basic equation form for species x in year y+1:

$$\hat{B}_{x,y+1} = \left(1 + \rho_x\right) s_{x,y} \hat{B}_{x,y} - \rho_x s_{x,y} s_{x,y-1} \hat{B}_{x,y-1} + \hat{R}_{x,y+1},$$

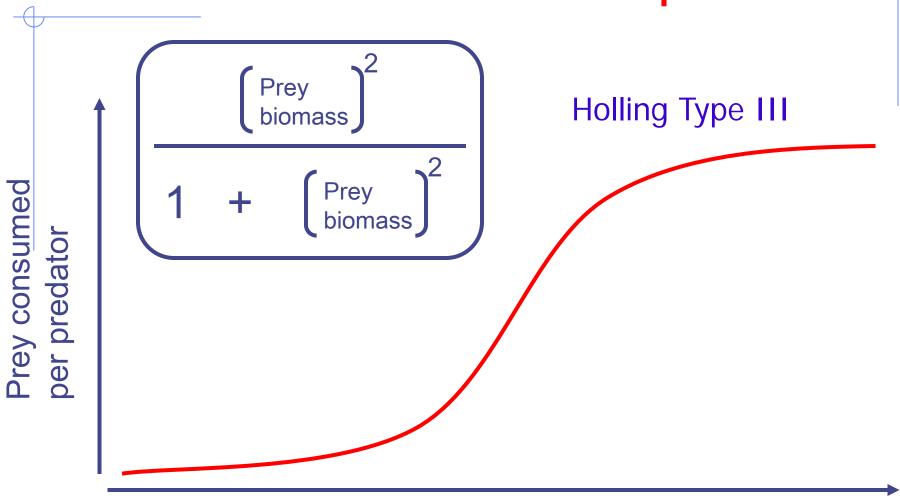

where:

 ρ_x = Ford growth parameter for species x,

 $s_{x,y}$ = surviving fraction of $\hat{B}_{x,y}$ in the previous year y

Recruitment for all species (except pollock) modeled using a Ricker stock-recruit model.

Predator Functional Response

Model Fitting

Data (NMFS)

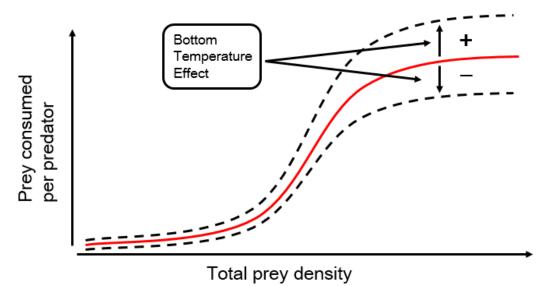

- Biomass estimates (adjusted for selectivity)
 - Summer bottom trawl survey
 - Summer mid-water echo-integration trawl (EIT) survey (pollock only)
- Annual catch estimates
- Biomass estimates of prey consumed by predator
- Models fitted by maximum likelihood
- Precision and bias of model parameters and biological reference points evaluated using Monte Carlo simulations

Effect of Temperature

Temperature effect modeled as:

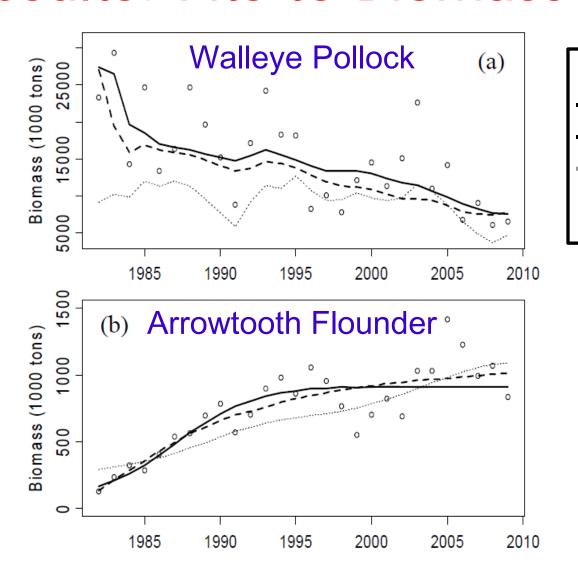

$$d_{za} = \bar{d}_{za} + e_{za} * T_B$$

where d_{za} is predation rate of predator z on juvenile age class a, d_{za} is the average predation rate at $T_B = 0$, and e_{za} is the slope.

Evidence for temperature-dependent predation was quantified using AIC_c.

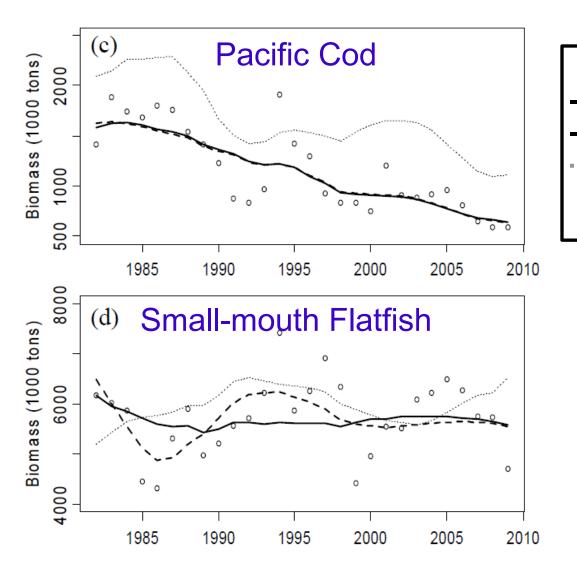

Results: Fits to Biomass

Observed
MBD Model
MDD Model
Single-species stock assess.

model

Results: Fits to Biomass

Observed
MBD Model
MDD Model
Single-species stock assess.

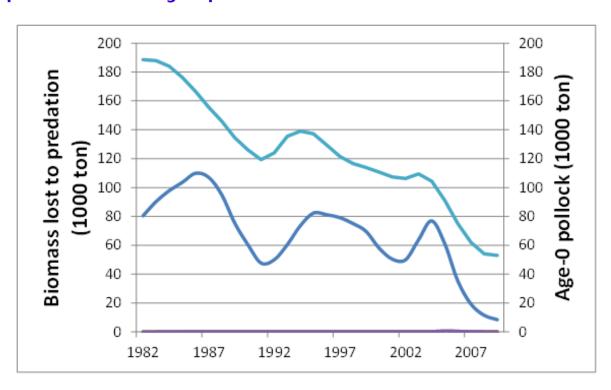

model

Other General Results

- MBD and MDD models predicted multispecies B_o, MSY, and F_{MSY} to be lower than the sum of estimates from single-species models
- MBD was the preferred model
 - Smaller bias in MSY and B_{MSY}
 - Biomass projections were more precise
 - MDD model produced biologically unrealistic biomass estimates when F>0.14
- → MBD model selected to examine temperature effects

Predation on Age-0 Pollock

Age-0 pollock biomass and age-0 biomass lost to predation by species

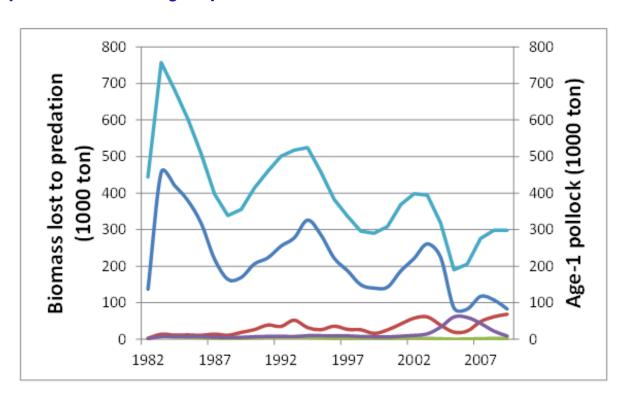

- —Juvenile pollock
- —Adult pollock
- —Arrowtooth
- —Pacific cod
- -Flatfish

43.0% of age-0 biomass lost to cannibalism

Predation on Age-1 Pollock

Age-1 pollock biomass and age-1 biomass lost to predation by species

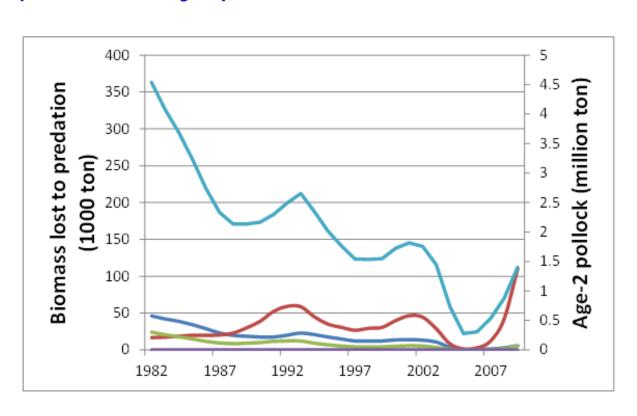

- —Juvenile pollock
- —Adult pollock
- —Arrowtooth
- —Pacific cod
- -Flatfish

63.6% of age-1 biomass lost to cannibalism

Predation on Age-2 Pollock

Age-2 pollock biomass and age-2 biomass lost to predation by species

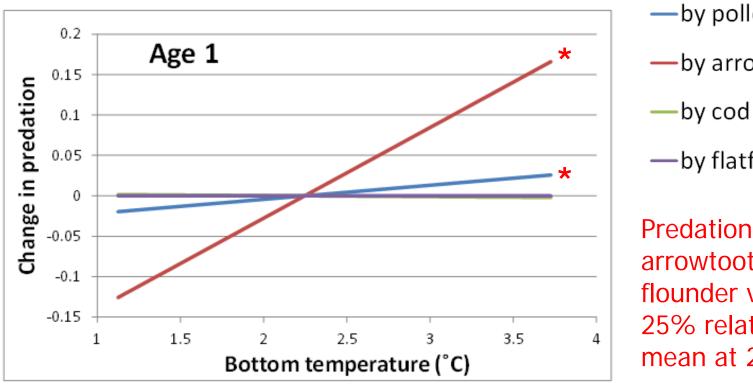

- Juvenile pollock
- —Adult pollock
- —Arrowtooth
- —Pacific cod
- —Flatfish

Predation lower for age-2 pollock

Temperature Effects on Predation of Age-1 Pollock

Warmer bottom temperatures increase predation on age-1 pollock by arrowtooth flounder and by adult pollock

by pollock

-by arrowtooth

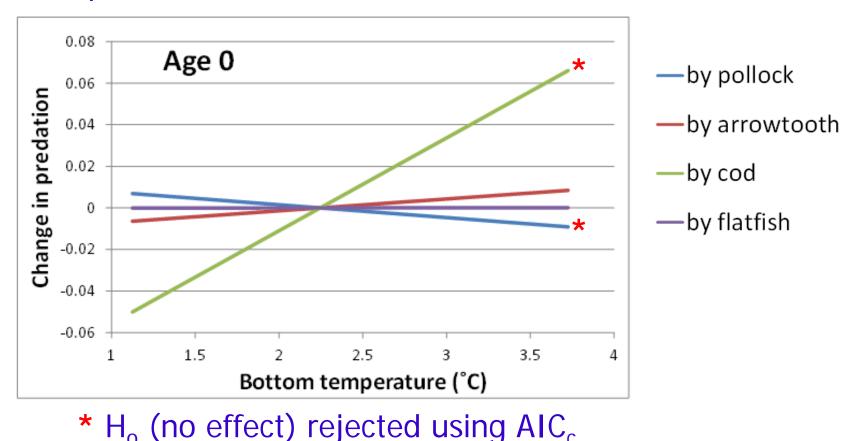

—by flatfish

Predation by arrowtooth flounder varies by 25% relative to mean at 2.25 C

* H_o (no effect) rejected using AIC_c

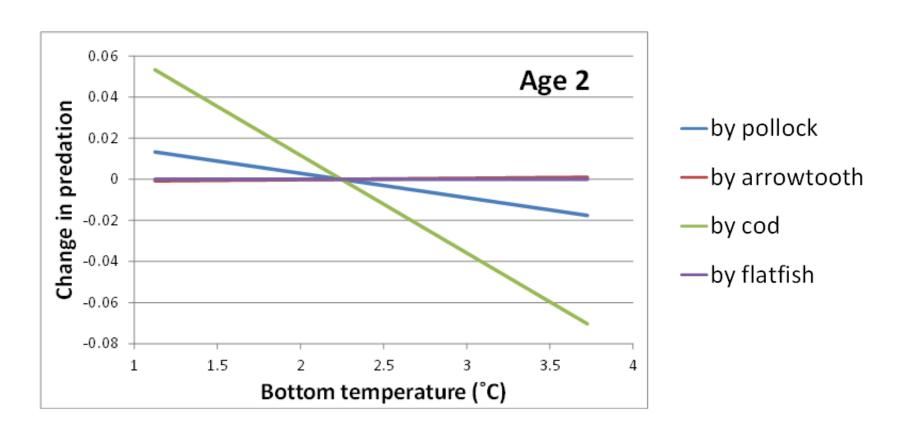

Temperature Effects on Predation of Age-0 Pollock

Warmer bottom temperatures increase predation on age-0 pollock by Pacific cod and decrease predation by adult pollock

Temperature Effects on Predation of Age-2 Pollock

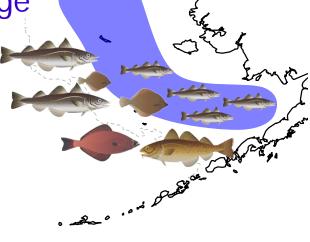

Non-significant negative effect of bottom temperature on predation of age-2 pollock by cod and adult pollock

- Both MBD and MDD models using predator-prey interactions successfully captured observed trends in survey biomass over 1982-2009
- Advantages and disadvantages of both approaches, but MBD performs better over all
- As with previous studies, multispecies biological reference points are lower than the sum of estimates from single-species assessments
- Multispecies models are useful to explore long-term effects of harvest strategies for one species on stock dynamics of other groundfish species
- Multispecies models are not yet ready for tactical advice, because many predation parameters are highly uncertain

- Cannibalism by adult pollock is most important form of predation on age-1 and age-0 pollock
- Of the 4 models most strongly supported by the data, the top 3 indicated a positive effect of temperature on predation of juvenile pollock

Results consistent with cold pool refuge

- Cannibalism by adult pollock is most important form of predation on age-1 and age-0 pollock
- Of the 4 models most strongly supported by the data, the top 3 indicated a positive effect of temperature on predation of juvenile pollock
- Results consistent with cold pool refuge
- Mueter et al. (2011) found evidence that warmer temperatures in late summer/autumn are associated with poor feeding conditions of age-0 pollock and reduced recruitment
- Warm temperatures lead to increased predation on age-1 pollock by two major predators

- Cannibalism by adult pollock is most important form of predation on age-1 and age-0 pollock
- Of the 4 models most strongly supported by the data, the top 3 indicated a positive effect of temperature on predation of juvenile pollock
- Results consistent with cold pool refuge
- Mueter et al. (2011) found evidence that warmer temperatures in late summer/autumn are associated with poor feeding conditions of age-0 pollock and reduced recruitment
- Warm temperatures lead to increased predation on age-1 pollock by two major predators
- → This may lead to a "double whammy" under global warming
